Notice

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

To Dr. John Bastyr and all the natural healers of the past and future who bring the "healing power of nature" to all the people of the world. Dr. Bastyr, the namesake for Bastyr University, exemplified the ideal physician/healer/teacher we endeavor to become in our professional lives.

We pass on a few of his words of wisdom to all who strive to provide the best of health care and healing: "Always touch your patients—let them know you care," and "Always read at least one research article or learn a new remedy before you retire at night."

Preface

In addition to updating all the content and research, the fourth edition of the *Textbook of Natural Medicine* (which has now been in publication since 1985) brings several new features: new chapters, a new utilization guide, comprised into one volume. The new chapters include topics such as female infertility, medicinal mushrooms, natural products and quality control, pregnancy health, Unani medicine, and vitamin K. In addition to new chapters, some chapters have been renamed for better consistency and some have been moved to Sections which we felt were more appropriate. To facilitate utilization, we have provided alphabetical tabs to help searching for specific diseases. Closely related diseases have been placed in a single chapter—for example depression, dysthymia, manic phase, and seasonal affective disorder are all located in the Affective Disorders chapter—so becoming familiar with these groupings is essential for finding specific diseases. There are twelve appendices that provide additional resources for the clinician. Finally, for the first time in over two decades the *Textbook of Natural Medicine* is back to a single volume. We worked with authors to make their writing more succinct and eliminate unnecessary content. We also reduced the length of Section VI by removing duplication of content from Section V in the therapeutics portion of the chapters. We hope you will be as pleased with the latest edition as we are.

Joseph E. Pizzorno
Michael T. Murray

Preface to the Third Edition

The scientific support for the philosophical and therapeutic foundation of natural medicine has evolved remarkably over the past 35 years. Concepts that were once considered "quaint" at best are now recognized as fundamental to good health and the prevention and treatment of disease. This textbook, with its roughly 10,000 citations to peer-reviewed research literature, provides well-documented standards of practice for natural medicine. Based on a sound combination of philosophy and clinical studies, this work provides the astute practitioner with a reliable informational resource to provide health care that identifies and controls the underlying causes of disease, is supportive of the body's own healing processes, and is considerate of each patient's unique biochemistry.

This textbook is composed of six sections, each focused on a fundamental aspect of the practice of natural medicine. "Philosophy of Natural Medicine" covers the history and conceptual basis of natural medicine. "Supplementary Diagnostic Procedures" provides a primer on diagnostic procedures not commonly taught in conventional medical schools. Diet analysis, food allergy testing, immune function assessment, fatty acid profiling, and hair mineral analysis are examples of these analytical procedures. The next section, "Therapeutic Modalities," provides a descriptive, practical, scientific, and historical review of the common modalities of natural medicine, including botanical medicine, nutritional therapy, therapeutic fasting, exercise therapy, hydrotherapy, counseling, acupuncture, homeopathy, and soft tissue manipulation. "Syndromes and Special Topics" considers underlying issues relevant to many diseases. "Pharmacology of Natural Medicines" covers the pharmacognosy, pharmacology, and clinical indications for the most commonly prescribed botanical medicines, special nutrients, and other natural agents. "Specific Health Problems" provides an in-depth natural medicine approach to more than 70 specific diseases and conditions. The comprehensive therapeutic rationales are well documented and based on the pathophysiology and causes of each condition.

PHILOSOPHY OF NATURAL MEDICINE

Nature is doing her best each moment to make us well. She exists for no other end. Do not resist. With the least inclination to be well, we should not be sick.

—Henry David Thoreau

8 Research in Natural Medicine, 93

One of the features of the various schools of natural medicine that differentiates them from conventional (allopathic) medicine is their strong philosophical foundation. The basic philosophical premise of naturopathic medicine, for example, is that there is an inherent healing power in nature and in every human being. We believe that a primary role of the physician is to bring out or enhance this innate healing power within his or her patients.

In many ways, this was the most difficult section of the textbook to write, since no comprehensive history of the social, political, and philosophical development of naturopathic medicine had ever been written, and even in the halcyon years of the 1920s and 1930s, the profession was never able to agree upon a concise philosophy. This situation has now changed.

We provide here a well-documented chapter detailing the roots of American naturopathy. After a century of maturation, the profession has now widely agreed to a comprehensive definition, set of principles, and system of case analysis that provide a systematic guide for the application of these concepts in a clinical setting.

The seven fundamental principles of naturopathic medicine are as follows:

1. The healing power of nature (*vis medicatrix naturae*)
2. First do no harm (*primum non nocere*)
3. Find the cause (*tolle causam*)
4. Treat the whole person
5. Preventive medicine
6. Wellness
7. Doctor as teacher

These principles translate into the following questions the practitioner applies when analyzing a case:

- What is the first cause; what is contributing now?
- How is the body trying to heal itself?
- What is the minimum level of intervention needed to facilitate the self-healing process?
- What are the patient's underlying functional weaknesses?
- What education does the patient need to understand why he or she is sick and how to become healthier?
- How does the patient's physical disease relate to his or her psychological and spiritual health?

We have further expanded on the philosophical basis of naturopathic medicine by having these concepts addressed by several authors whose backgrounds allow each of them a unique and, we believe, complementary insight into some of the fundamental questions of the goals of health care. Although the dominant school of medicine has essentially ignored these issues, we believe that the true physician cannot function without a sound philosophical basis to guide his or her actions. Without a more than superficial understanding of health and disease, the physician is more likely to function as a technician, temporarily alleviating symptoms while allowing the real disease to progress past the point of recovery.

CHAPTER 1

Eastern Origins of Integrative Medicine and Modern Applications

INTRODUCTION

Emaho, the Tibetan word for "wondrous," aptly describes the history of healing. The healing art of medicine is neither fixed in one theory of disease nor has its origins in a single body of perceptions. Its roots reveal rich and fascinating strands to its heritage. Each strand has developed potent theories and recommendations that inform prevention, illness, and treatment. These differences profoundly influence the vision and values among the members of a given culture—how to live well and how to address illness and health. Specifically, the contrasts in Eastern and Western approaches have been like strangers from afar, and now as of the twenty-first century, have become increasingly aware of each other in the evolving field of integrative medicine. Each has its advantages and limitations. Recognizing and skillfully combining the best of both approaches is an ongoing challenge and a noteworthy, positive advance for humanity.

In the past 20 years, medicine in the West has begun to diligently examine and resume its inclusion of indigenous traditions in medical practice. The term "integrative medicine" emerged in the early 1990s to describe a paradigm shift in modern medicine. Integrative medicine believes that drawing from multiple traditions better serves people, rather than using only one medical system. At the core of the integrative medicine movement in the West is how to examine indigenous healing modalities with scientific rigor for safety and efficacy, while retaining respect for their history and culture. With its emphasis on quality research evidence, integrative medicine modalities have gained further acceptance in the West, while having spawned a resurgence of indigenous medicines in their countries of origin.

Eastern healing traditions have made some of the greatest advances in integration with modern medicine. In this chapter, the authors briefly review the historical origins of Eastern and Western traditions and the contrast in their philosophies and examine some Eastern healing traditions more closely to better understand the application of Eastern healing modalities to modern medicine. Please note that the following is only an introduction to healing traditions that have had some success in practice with Western medicine. The authors encourage readers to actively engage in learning about other healing traditions specific to their local community.

Terminology

As the field of integrative medicine evolves, so does its terminology. "Modern medicine" in this chapter is used to describe the most mainstream medicine practiced and determined by the evolving scientific method, and "complementary and alternative medicine" (CAM) is used to describe practices that are not as well defined by the scientific method. Theories of medicine can also be grouped based on geographic origin: Western, originating from Greco-Roman philosophy, and Eastern, originating from Asian-Pacific philosophy. The term modern medicine implies fluidity, and it is fitting to use such terminology during the current period of expanding medical boundaries.

Reader's note: An essentially identical version of this chapter appeared in *Integrative Medicine: A Clinician's Journal (V2.2)* and is reprinted with approval from InnoVision Communications.

COMPARISON OF EASTERN AND WESTERN MEDICINE: ORIGINS AND PHILOSOPHIES

Historical Origins

The foundation of several Eastern healing traditions inextricably embraces the philosophies of early Eastern thought, those of Buddhism, Taoism, and Hinduism. These philosophies still provide the underpinnings for many contemporary Eastern cultures, allowing Eastern indigenous healing traditions to maintain widespread acceptance and practice. Several unique but related traditions developed in the East before the Christian era and are still heavily practiced today as discrete systems, including Chinese medicine, Ayurveda (traditional Indian medicine), and Tibetan medicine. Other Eastern traditions enjoy moderate practice in their areas of origin, including Persian medicine, medicine as set forth in the Dead Sea Scrolls, and folk shamanism and animism. Chinese Ayurveda, and Tibetan medicine will be more closely examined and compared later in this chapter, along with their current transformations in the West.

In contrast, modern medicine in the West developed quite independently from religious thought. It was, and continues to be, shaped by science. Modern scientific thought evolved from the Greek philosophers beginning with Euclid around 300 BC and later Plato, Socrates, and Aristotle. The mathematic theories of these Greek philosophers set the foundation for Renaissance scientists more than 1500 years later, who further developed the scientific method. The scientific method, which describes a constant process of empirical observation, logical reasoning, and skepticism to discern knowledge, is still the thought process used today to validate modern medicine.

It was not until later in the twentieth century, however, that the scientific method became the mainstay of modern medicine. In the early nineteenth century, modern medicine was pluralistic in nature as "professional care was mostly provided by botanical healers and midwives, supplemented by surgeons, barber-surgeons, apothecaries, and uncounted cancer doctors, bonesetters, inoculators, abortionists, and sellers of nostrums."[1] During much of this same period, the profession of naturopathy flourished to the benefit of many. At this time, the medical profession was still in its early stages in the United States. By the early to mid-twentieth century, medicine was much more narrowly defined through the scientific method. In the past 20 years, however, medicine in the United States has experienced another shift, arguably a shift again to the medical pluralism from more than 100 years ago. This raises the question: is this merely historical pattern or the birth of a unique era?

If modern medicine is experiencing yet another paradigm shift, the culture will necessarily move beyond the older ethos of the scientific method that defined its previous paradigm. Master Hong succinctly commented on this point, "What this [Qi Gong] master possesses isn't magic. It is just science that has not yet been examined."[2] In the twenty-first century, the culture of medicine is once again embracing its diverse options for health care, shifting yet again toward pluralism and reflecting the social landscape of a new generation. What is happening invites all healers to enlarge their ideas of disease and health and to welcome an expanded and deeper perspective.

Philosophies in Contrast

"Vive la différence." The differences in Eastern and Western medical traditions stem directly from their foundational differences in world views. Judith Farqhuar described these essential differences in world views as "the difference between a world of fixed objects and a world of transforming effects. Like the solid inertial world of modern natural science traditions, the … transformative world of Chinese medicine seems to exist prior to all argument, observation, and intervention. Perhaps with a certain discomfort, Western readers must acknowledge that 'their' abstractions about such things make as much sense as 'ours'."[3]

One of the most obvious and far reaching differences between Eastern and Western medical traditions is the concept of inter- and intra-personal relationships. Stemming from the Socratic model and Cartesian dualism, Western medicine heavily delineates between mind and body, between doctor and patient, and between healthy and diseased. In contrast, medicine originating in the East finds little distinction in these areas. Instead, it views continuity and balance as vital to health. Illness is defined by imbalances of patterns that should naturally be in harmony. Multiple aspects of the being, including the mind, body, and spirit, are integral to this harmony. In contrast, illness in modern Western medicine is described by a specific pathology, caused by discrete foreign pollutants, and often cured by another foreign element.

In its extreme, the patient is an accident attached to the disease under treatment.

The fundamental concepts of Eastern healing traditions are deeply embedded in the philosophies of their cultures. Consequently, they are perceptions, ideas, and values shared by most society members. Although health is integral to one's everyday life in Eastern societies, it is only one part of Western society. Likewise, health is defined in the East as a unity of individual, environmental, and societal factors. Although the Western definition of health has moved toward encompassing the physical, mental, social, and spiritual, each is still defined as a separate entity. In modern medical communities, divisions between physical and mental health and social work, are still at large, with these departments often not acting in concert.

These distinct differences shape the patient–doctor relationship. In Eastern traditions, a unique balance of these factors is critical to diagnosis and treatment of a patient's disharmony rather than disease. Physicians in Western medicine often look beyond the patient–doctor relationship to an external body of knowledge to diagnose and treat, guided by categories of symptoms. A general comparison of Eastern and Western concepts with regard to health is shown in Table 1-1.

Overview and Comparison of Eastern Traditions

As mentioned, although several indigenous healing traditions in the East have been preserved, Chinese, Ayurvedic, and Tibetan medicine remain among the most heavily practiced traditions in

TABLE 1-1 **Comparison of Western and Eastern Concepts**

	WESTERN	EASTERN
World views	Reductionist	Holistic
Mechanism of disorder	Pathologic mechanism	Imbalance of harmonies
Foundational structure	Logic, mathematics	Eastern religions and philosophies
Patient–doctor relationship	Access external body of knowledge for diagnosis and treatment	Unique balance critical to diagnosis and treatment

TABLE 1-2 **Comparison of Tibetan, Ayurvedic, and Chinese Medicine**

	TIBETAN	AYURVEDA	CHINESE
Health and disease	Defined by balance or imbalance of states		
Fundamental textures	3 humors: wind, bile, phlegm	3 humors (doshas): air, fire, water principles	Qi, blood, Shen
Principle of opposites	Hot/cold	Hot/cold	Yin/yang
5 Elements	Air, water, fire, ether, earth	Ether, water, fire, earth, air	Air, water, fire, metal, earth
Diagnostics	Pulse (most important), urine, tongue, morphology		
Treatment modalities	Behavioral (lifestyle, meditation), diet, herbals, external treatment	Dietary alterations, yoga, exercise, herbal formulas, surgical techniques	Acupuncture, herbals, Qi gong (acupuncture, massage)
Origin			
• Religious	Intimately related to Buddhist philosophy but stands on its own	Intimately related to Hindu philosophy but stands on its own	No formal tie to Taoism or Buddhism
• Text	*Gyu-zhi* (Tibetan rGyud-bzhi)	*Rig Veda* (second millennium BC) 800 BC	*Nei Jing* 2598 BC
Recent history (post-Newtonian, within past century)	Transformation by Chinese invasion	Enjoyed the greatest continuity	Transformation by Cultural Revolution

their respective regions. All three traditions stem largely from similar philosophical foundations; thus in all, health and disease are seen as inextricably interrelated. They play integral parts in the delicate balance of harmony and disharmony. Table 1-2 provides a comparison of these three traditions.

Origins

Tibetan medicine and Ayurvedic medicine have similar historical origins, since Ayurveda is the root of Tibetan medicine. Ayurvedic origins are found as early as the second millennium BC in the *Rig Veda*, with its second classical stage in the Brahmanic period in 800 BC, where it continued as an unbroken lineage until the Moslem conquest of India in the thirteenth century. During that time in the sixth century BC, the historical Buddha, Shakyamuni, was born in India, and after achieving Enlightenment under a Bodhi tree in Bodhgaya and delivering the teachings of the Four Noble Truths, Buddhism was born.*

The Tibetan medical tradition offers that the Buddha, often called the "Great Physician," taught the medical texts himself, including the *Gyu-zhi*, the most important Tibetan medical text. The Sanskrit version of the *Gyu-zhi*, however, was probably not written until around 400 AD.[4] Although some scholars may debate whether the historical Buddha's teachings are the precise origin of Tibetan and, thus, Ayurvedic medicine, Buddhism's influence on these two healing traditions is unquestionable.

Like Ayurveda, the origins of Chinese medicine date back to at least the second millennium BC, to the era of the great Yellow Emperor, Huangdi (2698–2598 BC). The classic medical text written during his reign is *Huangdi Nei Jing (The Yellow Emperor's Inner Canon)*. Yet perhaps of more influence to Chinese medicine known today is the *Nan Jing (The Classic of Difficult Issues)*, written around the first or second century AD. As Nolting notes in Chapter 31 on "Acupuncture" in this edition, the *Nei Jing* deals more with "demonological medicine and religious healing," whereas the *Nan Jing* developed Chinese medicine as an original system, with well-defined and organized principles, diagnostics, and therapeutics.[5]

Chinese medicine also witnessed various transformations, most notably its recent evolution into Traditional Chinese Medicine (TCM), the modern form of Chinese medicine practiced in China and worldwide. Influenced by the advent of modern science, Chinese medicine was required during the 1950s to establish increased legitimacy in the face of the new Marxist ideology, which emphasized "natural science" and delegitimized Confucian influences. Initially, the People's Republic of China denounced folk, demonic, and Buddhist temple medicine.[6] However, in 1951, Mao Zedong revived and then canonized portions of the tradition with his "Chinese medicine is a great treasure-house" speech.[7] In Mao's Cultural Revolution, Chinese medicine was transformed to TCM and embraced as a means to preserve the "spirit of a nation." The "new medicine" movement highlighted traditional medicine's ability to arouse one's own bodily defenses against illness while excluding metaphysical ideologies. TCM thus embodied one general theory of Chinese medicine and discouraged diverse readings and interpretations by practitioners and students.

Of the three traditions, Tibetan medicine enjoyed the most continuity in lineage until the Chinese invasion in 1959. With the Moslem invasion of India in the thirteenth century, much of the Ayurvedic medical system was destroyed, along with many Buddhist texts. Fortunately, by the seventh century AD, Ayurvedic medicine had traveled to Tibet and was safely preserved in the Himalayan Mountains. Once in Tibet, Buddhism and its medicine first adapted to the indigenous shamanic religious culture, Bon, whose greatest contribution to the Tibetan medical system was its knowledge of the indigenous medical herbs of the sub-Himalayan plateaus. With King Strongtsan Gampo's formal introduction of Buddhism to Tibet in the early seventh century, the influence of Buddhism on its medicine flourished. This continued up until the Chinese invasion in 1959.

Despite its isolation in practice, Tibetan medicine shares several principles with other Eastern healing traditions. Its strongest ties are with Chinese medicine to the north and Ayurvedic medicine to the south. Eastern traditions of healing are undoubtedly intertwined in a rich tapestry, stemming partly from an extraordinary

*Lineage refers to the descendants of a common ancestor considered to be the founder of the line.

meeting of healers. During the seventh century, the Tibetan King Gampo held the world's first recorded international medical conference. Noted physicians from India, China, Greece, Nepal, Persia, and Mongolia dialogued in a cross-cultural exchange, and texts from each medical tradition were translated.

Fundamental Philosophies: Tools to Assess Balance

The notion that ill health stems from the imbalance of certain fundamental forces or "textures" stands at the core of many Eastern healing traditions. Although the traditions may vary as to which fundamental forces, textures, or elements are involved in diagnosis and treatment, certain philosophies are shared. In these, the five elements, fundamental textures, and principles of opposites govern the universe. The five-element theory is the most common approach used to diagnose and restore health. The five elements are commonly understood to define, control, and at the same time be governed by a constellation of internal and external phenomena. These phenomena include human emotions, human senses, body organs, and climate.

Humoral pathology, central to Ayurvedic, Tibetan, Persian, and Greek systems, is the core principle that unifies the mind with the body and the individual with his environment. It defines the balance or imbalance of the textures that influence one's state of health. These humors define an array of biological, physiopathologic, and psychological phenomena related to the body, the mind, and the environment. In both Tibetan and Ayurvedic medicine, three humors, or primary qualities, maintain aspects of health. In Tibetan medicine, they are *Vayu* (Tibetan *Rlung*), *Pitta* (Tibetan *Khrid*), and *Kapha* (Tibetan *Bad-kan*), translated as "wind," "bile," and "phlegm," respectively. Yet the English translation is imprecise and limits the meanings of wind, bile, and phlegm principles, which further describe the mind, energy, and inert matter. Analogies can be drawn using conventional physics. Wind can be compared with kinetic energy, bile with caloric energy, and phlegm with mass energy. With reference to personality, those governed by air tend to be wiry and impulsive; bile types are muscular and quick to anger; and those ruled by phlegm are normally heavy set and tend to avoid conflict. Additionally, the humors are the products of the three delusions, which are the root cause of all suffering in the Buddhist tradition: phlegm, a product of ignorance, bile from anger, and wind from attachment. Understanding the humors as products of the three delusions underlines the interrelationship between Buddhism as a spiritual practice and the healing professions.

In Ayurvedic medicine, these humors are the three *Doshas*, known as *Vat* (or air principle), *Pit* (or fire principle), and *Kaph* (or water principle), and they carry specific actions. *Vat* is the bodily air principle and governs movement; *Pit* is the bodily fire principle that controls metabolism; and *Kaph* is the biological water principle that provides physical structure. These principles are also associated with the metabolic activities of anabolism, catabolism, and metabolism. In addition, they are associated with certain personalities and certain physical characteristics of dry or oily, light or heavy, and hot or cold. For a more complete discussion of the *Doshas* and their related properties and functions, see Chapter 32.

Chinese medicine encompasses a similar principle that certain fundamental qualities must be in balance to achieve a healthy state. These fundamental textures are the universal Qi, Blood *(xue),* Essence *(jing),* and Spirit *(shen).* Like the humors of Tibetan and Ayurvedic medicine, Qi is universal and encompasses and connects all animate phenomena internally (body, mind, organs, senses) and externally (organism to environment). Qi generates change both on a small scale and in the larger picture of Yin and Yang, those opposite forces, for example, of light and dark, female and male, that embody all organisms. Qi has five major functions: movement, protection, harmonious transformation, stability and retention, and warming of the body. The definition of blood in Chinese medicine goes beyond the physical concept of blood in Western medicine, since it is the Yin complement to the clinical Yang Qi, functioning to nourish, circulate, and moisten the body. Essence is specific to organic life and slowly perpetuates life forward. Although Qi is the fluid movement of ordinary time, Essence spans a lifetime and embodies all characteristics involved with birth, maturation, and death. Lastly, Spirit is unique to human life but is beyond mind-consciousness. It is what prompts humanity and relationships with one's self and other humans, and it examines all facets of humanity—moral, social, mental, physical, and emotional.

Although the concept of Yin and Yang is at the core of Chinese medicine, principles of opposites to achieve balance and optimal health are central to all three traditions. The Tibetan and Ayurvedic systems employ "hot" and "cold" to depict opposites. These fundamental opposites, fundamental textures, and five elements are intricately related to one another, providing a holistic framework in which to consider health and illness.

Diagnostics and Treatments

In accordance with its foundational philosophies, diagnostics in Eastern traditions take into account the person as a whole. The patient's physiologic characteristics, mental dispositions, and other personal, social, economic, and environmental details are assessed. In addition, diagnosis includes the following examinations: general physical, pulse, urine, tongue, eyes, skin, and ears.

The core principle in treatment is to restore the person's health to equilibrium through several behavioral, lifestyle, diet, manual, and medicinal treatment approaches. Treatment methods in the Tibetan tradition are arranged in a hierarchy of usage: (1) behavioral practices (lifestyle, meditation), (2) diet, (3) herbal medicines, and (4) external treatments (acupuncture, massage, moxa, and surgery). Treatment therapies in Ayurveda include dietary alterations, yoga, exercise, herbal formulas, and surgical techniques. Ayurveda places special emphasis on diet as a modality, since it considers the human body a mental and physical product of the food consumed. Main treatment methods in Chinese medicine include acupuncture, herbal medicine, and sometimes Qi Gong.

MODERN APPLICATIONS: THE AGE OF INTEGRATION

[The interpreter's] task is rather to seize the vital conception of the art-work, to blend it with his own ego and the views of his period, and thus to imbue it with life and effectiveness. His artistry is a product of its mental culture. It develops and changes with the evolution of artistic requirements. His formative and emotional powers are derived from the spirit of the epoch to which he belongs.

Much that charmed former generations has no effect in ours; so much is part and parcel of its passing. Only what is exalted over time and place remains as eternal gain; and here, again, another generation finds new treasures that earlier ones passed by unheeding. This is the unfailing criterion of true greatness, that its creations continually beget ever-new, ever-changing values, that they bring to each successive generation new revelations.

—Max Spicker, 1912

As the social landscape changes, the culture of medicine continually redefines what is considered "conventional." Numerous recent studies have shown that since the early 1990s, consumers have been demanding alternatives to modern care.[8] Only since then has integrated medicine, including naturopathy, penetrated the Ivory Tower and research institutions in the United States. Driven by scientific advancement and a need for increased knowledge, this movement toward more pluralistic medicine has now brought us beyond the age of information and into the "age of integration."

With the current plethora of health information, it is becoming more apparent that optimal healing is not the property of any one tradition or system. Integrative clinics that incorporate multiple healing systems now thrive throughout the country and at major academic medical institutions. Employers and managed care agencies are beginning to offer coverage for acupuncture, chiropractic, naturopathy, and massage services. The Academic Consortium for Integrative Medicine has been formed among top-ranked medical schools to integrate CAM into their curricula. The National Institutes of Health has devoted an institute just for CAM with a budget of over $130 million.* Some medical residencies now include CAM in their training, and fellowships in integrative medicine now exist.

Despite the recent explosion of integrative medicine entering research, education, and clinical arenas, several barriers still limit the growth of integrative medicine in the United States. The most pressing and present barrier to clinical integration is reimbursement. To persuade insurers to cover the costs of CAM therapies, research evidence built on rigorous clinical trials and data that demonstrate cost efficacy of these modalities are necessary.

Perhaps an even greater barrier to integration is the challenge of how to establish safe and effective practices for these modalities, while carefully preserving the lineage of indigenous traditions. To examine this issue, the authors outline the birth and evolution of indigenous traditions as medical professions in the United States and later provide units on clinical practice, risk management, professional communications, practice management, and research that serve as essential tools for integration.

The current dilemma in the development of these CAM professions is how to perpetuate lineages during this integration with other health care professions, while not lowering standards for CAM practitioners. This present boom in alternative health care has resulted in the current state of integrative medicine: a confusing situation with too many practitioners offering a wide range of skills but leaving consumers without tools to decipher which are the most effective or true to tradition.

The middle path must be taken by raising the bar for practice standards. If the bar is too low, traditions will no longer be protected and they will not be as efficacious in practice. Consequently, practitioners may not be appreciated by either patients or traditional providers. If the bar is too high, few will find access and few will be able to practice. Either way, invaluable traditions may be lost.

The Birth and Evolution of a Medical Profession in the United States: Complementary and Alternative Medicine Professions

In the last years of the twentieth century, the United States witnessed the beginning transformations of indigenous healing traditions into CAM professions. After the counter-culture years of the 1960s and 1970s that challenged institutionalized medicine, interest in "natural healing" practices surged. As a result, chiropractic care and naturopathy were the first traditions to become formalized in modern medicine. Since then, Chinese medicine—via acupuncture—has made the largest entrance into health care in the United States, with more than 50 TCM and acupuncture schools in the United States and Canada accredited by the Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM), adoption of licensure laws in the majority of states, and an increasing number of insurers offering coverage. A far second to Chinese medicine has been the development of Ayurvedic and Tibetan medicine, which are still in the early phases of their evolution as professions in the United States.

Every medical tradition, even current scientific-based modern medicine, began at the margin and progressed through a similar cycle to become an established practice or profession. Currently, CAM modalities are finding similar challenges as they endure this evolution toward becoming established professions. Typically, in stage 1, lone practitioners of the tradition arrive in the United States and provide informal workshops to the public and interested health care providers. These CAM practitioners practice their traditions informally. Stage 2 develops only after public and provider acceptance of safety and efficacy. Stage 2 marks the development of professional education and associations, provides standards for school accreditation and credentialing, and, ultimately, licensure by state boards. With regulation through professional associations, third-party payers become amenable to insurance reimbursement for CAM treatments. Finally, stage 3 results in set state and national standards for the profession, including education, practice, and methods to evaluate safety and efficacy, as well as widespread acceptance and practice. In this current era, the accomplishment of stage 3 is inherently dependent on the respectful and appropriate blending of these CAM traditions with the dominant medical paradigm based in science.

At this time in the United States, the professions of naturopathy, chiropractic, acupuncture, and massage are in early stage 3 of their professional and legislative developments, where accredited schools in all these fields have been undoubtedly established and licensure is being governed by state boards. For instance, acupuncture currently has two established organizations that help to set standards for training and practice: the ACAOM and the National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM). ACAOM is recognized by the U.S. Department of Education to accredit first professional master's degree and master's level programs in acupuncture and Oriental medicine and is currently petitioning to begin accrediting postgraduate, clinical doctoral programs. Acupuncturists are currently licensed according to state boards, but licensure laws vary from state to state. Many states recognize NCCAOM certification as a national standard, and thus practitioners can earn licensure with NCCAOM certification in these states. Acupuncture, as practiced by over 5000 medical doctors in the United States, is currently the fastest growing medical specialty. The American Academy for Medical Acupuncture now offers specialty board certification in the field. Nevertheless, although there is now some insurance coverage for modalities like acupuncture, barriers such as standardization in education, practice, and research still exist.

TOOLS FOR INTEGRATION

As providers of CAM services join professional networks and become increasingly integrated into conventional health delivery, the CAM professions gain both credibility and exposure.

*Monetary figure from National Institutes of Health, Office of Budget website at http://officeofbudget.od.nih.gov/br.html for fiscal year 2012.

Integration brings with it a new set of responsibilities. Utilization is growing and evolving so quickly that the educational institutions preparing CAM providers for licensure are hard pressed to keep up with the trend. As a result, CAM provider education often does not fully prepare its graduates to meet the growing expectations of the public, the medical community, or the legal system. Providers must gain competency in "tools for integration" that lead to a new set of skills for clinical practice, risk management, professional communications, practice management, and research. These tools include, but are not limited to, those listed in Box 1-1.

The emerging field of integrative medicine has arrived at the end of the beginning. It is no longer simply a vision of what could be. Billions of dollars are now spent out of pocket for several hundred million visits to integrative providers and for herbs and nutraceuticals each year. The majority of medical schools now offer some form of CAM education for physicians in training. Yet until now, the consumer has carried the day. As physicians move forward into the twenty-first century, they are ready to enter the beginning of the middle. The transition is rapidly underway, and clinical models for integration and quality studies demonstrating efficacy and cost offsets are imperative to its success.

In practice, it is also increasingly necessary to build bridges between the indigenous community, evolving CAM professions, and established medical institutions. Researchers, academicians, and health care professionals from multiple backgrounds need to understand the challenges in integration to provide optimal health with wisdom for this generation and the next. Only through partnership can the best medicine be offered and this evolution in the culture of health care be assisted.

BOX 1-1 **Tools for Integration**

Clinical
Prevention and identification of medical emergencies in the CAM clinic
Prevention and appropriate medical responses to adverse reactions of CAM therapies
Recommendations for interdisciplinary care of common complaints
Guidelines for selected scope of practice issues
Herbs as nutraceuticals

Risk Management
Malpractice
Informed consent
Expert testimony
Charting
Regulatory issues
Insurance

Professional Communications
Patient presentations
Referral protocols
Operations
Human resources
Patient relations
Using information technology

Research
A survey of conventional research tools
Customizing conventional research tools to study CAM
Evaluating research publications
Using research findings
Performing original research

CAM, Complementary and alternative medicine.

Integration of Care, *16*

In this chapter, the basic principles, constructs, and methodology of functional medicine are reviewed. It is not the purpose of this chapter to recapitulate the range and depth of the science underlying functional medicine; books and monographs covering that material in great detail are already available for the interested clinician and for use in health professional schools (see Bibliography at the end of the chapter). The purpose is to describe how functional medicine is organized to deliver personalized systems medicine and is equipped to respond to the challenge of treating complex chronic disease more effectively.

WHAT IS FUNCTIONAL MEDICINE?

Functional medicine encompasses a dynamic approach to assessing, preventing, and treating complex chronic disease. It helps clinicians of all disciplines identify and ameliorate dysfunctions in the physiology and biochemistry of the human body as a primary method of improving patient health. This model of practice emphasizes that chronic disease is almost always preceded by a period of declining function in one or more of the body's physiologic organizing systems. Returning patients to health requires reversing (or substantially improving) the specific dysfunctions that contributed to the disease state. Those dysfunctions are, for each of us, the result of lifelong interactions among our environment, our lifestyle choices, and our genetic predispositions. Each patient, therefore, represents a unique, complex, and interwoven set of influences on intrinsic functionality that, over time, set the stage for the development of disease or the maintenance of health. To manage the complexity inherent in this approach, functional medicine has adopted practical models for obtaining and evaluating clinical information that leads to individualized patient-centered therapies.

Historically, the word "functional" was used somewhat pejoratively in medicine. It implied a disability associated with either a geriatric or psychiatric problem. The authors suggest, however, that this is a very limited definition of an extremely useful word. Medicine has not really produced an efficient method for identifying and assessing changes in basic physiologic processes that produce symptoms of increasing duration, intensity, and frequency, although it is known that such alterations in function often represent the first signs of conditions that, at a later stage, become pathophysiologically definable diseases. By broadening the use of functional to encompass this view, functional medicine becomes the science and art of detecting and reversing alterations in function that clearly move a patient toward chronic disease over the course of a lifetime.

One way to conceptualize where functional medicine falls in the continuum of health and health care is to examine the functional medicine "tree." In its approach to complex chronic disease, functional medicine encompasses the whole domain represented by the graphic shown in Figure 2-1, but first addresses the patient's core clinical imbalances (found in the functional physiologic organizing systems), the fundamental lifestyle factors that contribute to chronic disease, and the antecedents, triggers, and mediators that initiate and maintain the disease state. Diagnosis, of course, is part of the functional medicine model, but the emphasis is on understanding and improving the functional core of the human being as the starting point for intervention.

Functional medicine clinicians focus on restoring balance to the dysfunctional systems by strengthening the fundamental physiologic processes that underlie them and by adjusting the environmental and lifestyle inputs that nurture or

FIGURE 2-1 The continuum of health and health care: the functional medicine tree. (Courtesy of the Institute for Functional Medicine.)

impair them. This approach leads to therapies that focus on restoring health and function, rather than simply controlling signs and symptoms.

Principles

Seven basic principles characterize the functional medicine paradigm:

- Acknowledging the biochemical individuality of each human being, based on the concepts of genetic and environmental uniqueness
- Incorporating a patient-centered rather than a disease-centered approach to treatment
- Seeking a dynamic balance among the internal and external factors in a patient's body, mind, and spirit
- Addressing the web-like interconnections of internal physiologic factors
- Identifying health as a positive vitality—not merely the absence of disease—and emphasizing those factors that encourage a vigorous physiology
- Promoting organ reserve as a means of enhancing the health span, not just the life span, of each patient
- Staying abreast of emerging research—a science-using approach

Lifestyle and Environmental Factors

The building blocks of life, as well as the primary influences on them, are found at the base of the functional medicine tree graphic (see Figure 2-1). When we talk about influencing gene expression, we are interested in the interaction between lifestyle and environment in the broadest sense and any genetic predispositions with which a person may have been born—including the epigenome.* Many environmental factors that affect genetic expression are (or appear to be) a matter of choice (such as diet and exercise); others are very difficult for the individual patient to alter or escape (air

*Epigenetics—the study of how environmental factors can affect gene expression without altering the actual DNA sequence and how these changes can be inherited through generations.

and water quality, toxic exposures); and still others may be the result of unavoidable accidents (trauma, exposure to harmful microorganisms). Some factors that may appear modifiable are heavily influenced by the patient's economic status—if you are poor, for example, it may be impossible to choose more healthful food, decrease stress in the workplace and at home, or take the time to exercise and rest properly. Existing health status is also a powerful influence on the patient's ability to alter environmental input. If you have chronic pain, exercise may be extremely difficult; if you are depressed, self-activation is a major challenge.

The influence of these lifestyle and environment factors on the human organism is indisputable,[1,2] and they are often powerful agents in the battle for health. Ignoring them in favor of the quick fix of writing a prescription—whether for pharmaceutical agents, nutraceuticals, or botanicals—means the cause of the underlying dysfunction may be obscured but not eliminated. In general terms, the following factors should be considered when working to reverse dysfunction or disease and restore health:

- Diet (type, quality, and quantity of food; food preparation; calories, fats, proteins, carbohydrates)
- Nutrients (both dietary and supplemental)
- Air and water
- Microorganisms (and the general condition of the soil in which food is grown)
- Physical exercise
- Trauma
- Psychosocial and spiritual factors, such as meaning and purpose, relationships, work, community, economic status, stress, and belief systems
- Xenobiotics
- Radiation

Fundamental Physiologic Processes

There are certain physiologic processes that are necessary to life. These are the "upstream" processes that can go awry and create "downstream" dysfunctions that eventually become disease entities. Functional medicine requires that clinicians consider these in evaluating patients, so that interventions can target the most fundamental level possible. These processes are:

1. Communication
 - Outside the cell
 - Inside the cell
2. Bioenergetics/energy transformation
3. Replication/repair/maintenance/structural integrity
4. Elimination of waste
5. Protection/defense
6. Transport/circulation

These fundamental physiologic processes are usually taught early in health professions curricula, where they are appropriately presented as the foundation of modern, scientific patient care. Unfortunately, subsequent training in the clinical sciences often fails to fully integrate knowledge of the functional mechanisms of disease with therapeutics and prevention, emphasizing organ system diagnosis instead.[3] Focusing predominantly on organ system diagnosis without examining the underlying physiology that produced the patient's signs, symptoms, and disease often leads to managing patient care by matching diagnosis to pharmacology. The job of the health care provider then becomes a technical exercise in finding the drug or procedure that best fits the diagnosis (not necessarily the patient), leading to a significant curtailment of critical thinking pathways: "Medicine, it seems, has little regard for a complete description of how myriad pathways result in any clinical state."[4]

Even more important, pharmacologic treatments (and even natural remedies) are often prescribed without careful consideration of their physiologic effects across all organ systems, physiologic processes, and genetic variations.[5] Pharmaceutical companies exploit this weakness. We do not see drug advertisements that urge the practitioner to carefully consider the impact of all other drugs being taken by the patient before prescribing a new one! The marketing of drugs to specific specialty niches, and the use of sound bite sales pitches that suggest discrete effects, skews health care thinking toward this narrow, linear logic, as notably exemplified by the cyclooxygenase-2 inhibitor drugs that were so wildly successful on their introduction, only to be subsequently withdrawn or substantially narrowed in use due to collateral damage.[6,7]

Core Clinical Imbalances

The functional medicine approach to assessment, both before and after diagnosis, charts a course using different navigational assumptions. Every health condition instigates a quest for information centered on understanding when and how the specific biological system(s) under examination spun out of control to begin manifesting dysfunction and/or disease. Analyzing all the elements of the patient's story, the signs and symptoms, and the laboratory assessment through a matrix focused on functionality requires analytic thinking and a willingness on the part of the clinician to reflect deeply on underlying biochemistry and physiology. The foundational principles of how the human organism functions—and how its systems communicate and interact—are essential to the process of linking ideas about multifactorial causation with the perceptible effects called disease or dysfunction.

To assist clinicians in this process, functional medicine identified and organized a set of core clinical imbalances that are linked to the fundamental physiologic processes (organizing systems). These serve to marry the mechanisms of disease with the manifestations and diagnoses of disease. Many common underlying pathways of disease are reflected in these clinical imbalances. The following list of imbalanced systems and processes is not definitive, but some of the most common examples are provided. We recommend that the organizing systems be considered in the order as shown in the following:

Assimilation Imbalances
- Digestion
- Absorption
- Microbiota/gastrointestinal
- Respiration

Defense and Repair Imbalances
- Immune system
- Inflammatory processes
- Infection and microbiota

Energy Imbalances
- Energy regulation
- Mitochondrial function

Biotransformation and Elimination Imbalances
- Toxicity
- Detoxification

Communication Imbalances
- Endocrine
- Neurotransmitter
- Immune messengers
- Cognition

Structural Integrity Imbalances
- From the subcellular membranes
- To the musculoskeletal system

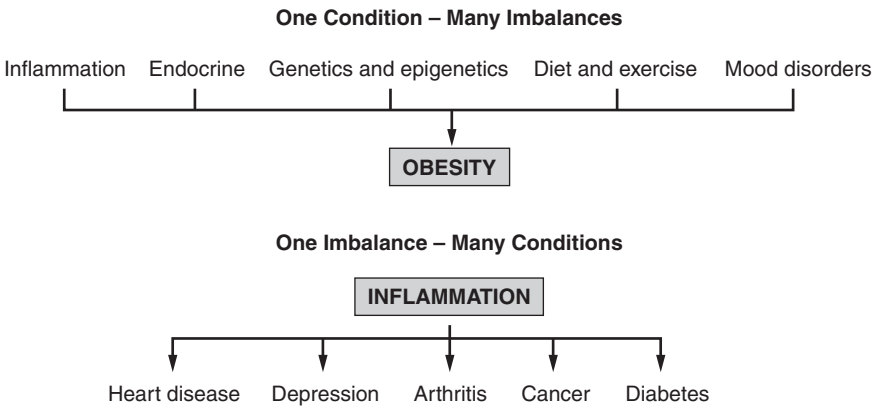

FIGURE 2-2 Core clinical imbalances—multiple influences. (Courtesy of the Institute for Functional Medicine.)

Using this construct, it becomes much clearer that one disease and/or condition may have multiple causes (i.e., multiple clinical imbalances), just as one fundamental imbalance may be at the root of many seemingly disparate conditions (Figure 2-2).

The most important precept to remember about functional medicine is that restoring balance—in the patient's lifestyle and/or environment and in the body's fundamental physiologic processes—is the key to restoring health.

Antecedents, Triggers, and Mediators*

What modern science has taught us about the genesis of disease can be represented by three words: triggers, mediators, and antecedents. Triggers are discrete entities or events that provoke disease or its symptoms. Microbes are an example. The greatest scientific discovery of the nineteenth century was the microbial etiology of the major epidemic diseases. Triggers are usually insufficient in and of themselves for disease formation; however, host response is an essential component.

It is, therefore, the functional medicine practitioner's job to know not just the patient's ailments or diagnoses, but the physical and social environment in which sickness occurs, the dietary habits of the person who is sick (present diet and pre-illness diet), his or her beliefs about the illness, the impact of illness on social and psychological function, factors that aggravate or ameliorate symptoms, and factors that predispose to illness or facilitate recovery. This information is necessary for establishing a functional treatment plan.

Identifying the biochemical mediators that underlie host responses was the most productive field of biomedical research during the second half of the twentieth century. Mediators, as the word implies, do not cause disease. They are intermediaries that contribute to the manifestation and/or continuation of disease. Antecedents are factors that predispose to acute or chronic illness. For a person who is ill, antecedents form the illness diathesis. From the perspective of prevention, they are risk factors. Knowledge of antecedents provides a rational structure for the organization of preventive medicine and public health.

Medical genomics seeks to better understand disease by identifying the phenotypic expression of disease-related genes and their products. The application of genomic science to clinical medicine requires the integration of antecedents (genes and the factors controlling their expression) with mediators (the downstream products of gene activation). Mediators, triggers, and antecedents are not only key biomedical concepts, they are also important psychosocial concepts. In person-centered diagnosis, the mediators, triggers, and antecedents for each person's illness form the focus of clinical investigation.

Antecedents and the Origins of Illness

Understanding the antecedents of illness helps the physician understand the unique characteristics of each patient as they relate to his or her current health status. Antecedents may be thought of as congenital or developmental. The most important congenital factor is gender: women and men differ sharply in susceptibility to many disorders. The most important developmental factor is age; what ails children is rarely the same as what ails the elderly. Beyond these obvious factors lies a diversity as complex as the genetic differences and separate life experiences that distinguish one person from another.

Triggers and the Provocation of Illness

A trigger is anything that initiates an acute illness or the emergence of symptoms. The distinction between a trigger and a precipitating event is relative, not absolute; the distinction helps organize the patient's story. As a general rule, triggers only provoke illness as long as the person is exposed to them (or for a short while afterward), whereas a precipitating event initiates a change in health status that persists long after the exposure ends.

Common triggers include physical or psychic trauma, microbes, drugs, allergens, foods (or even the act of eating or drinking), environmental toxins, temperature change, stressful life events, adverse social interactions, and powerful memories. For some conditions, the trigger is such an essential part of our concept of the disease that the two cannot be separated; the disease is either named after the trigger (e.g., strep throat) or the absence of the trigger negates the diagnosis (e.g., concussion cannot occur without head trauma). For chronic ailments like asthma, arthritis, or migraine headaches, multiple interacting triggers may be present. All triggers, however, exert their effects through the activation of host-derived mediators. In closed-head trauma, for example, activation of *N*-methyl-D-aspartic acid receptors, induction of nitric oxide synthase, and liberation of free intraneuronal calcium determine the late effects. Intravenous magnesium at the time of trauma attenuates severity by altering the mediator response.[8,9] Sensitivity to different triggers often varies among persons with similar ailments. A prime task of the functional practitioner is to help patients identify important triggers for their ailments and develop strategies for eliminating them or diminishing their virulence.

*This section was excerpted and adapted from Galland L. Patient-centered care: antecedents, triggers, and mediators. In *Textbook of Functional Medicine,* Institute of Functional Medicine, Gig Harbor, WA, Ch. 8.

BOX 2-1 **Common Illness Mediators**

Biochemical Hormones
Neurotransmitters
Neuropeptides
Cytokines
Free radicals
Transcription factors

Subatomic
Ions
Electrons
Electrical and magnetic fields

Cognitive/Emotional
Fear of pain or loss
Feelings or personal beliefs about illness
Poor self-esteem, low perceived self-efficacy
Learned helplessness
Lack of relevant health information

Social/Cultural
Reinforcement for staying sick
Behavioral conditioning
Lack of resources due to social isolation or poverty
The nature of the sick role and the doctor/patient relationship

Mediators and the Formation of Illness

A mediator is anything that produces symptoms or damages tissues of the body, including certain behaviors. Mediators vary in form and substance. They may be biochemical (e.g., prostanoids and cytokines), ionic (e.g., hydrogen ions), social (e.g., reinforcement for staying ill), psychological (e.g., fear), or cultural (e.g., beliefs about the nature of illness). A list of common mediators is presented in Box 2-1. Illness in any single person usually involves multiple interacting mediators. Biochemical, psychosocial, and cultural mediators interact continuously in the formation of illness.

CONSTRUCTING THE MODEL

Assessment

Combining the principles, lifestyle and environment factors, fundamental physiologic processes, antecedents, triggers, mediators, and core clinical imbalances creates a new information gathering and sorting architecture for clinical practice—in effect a new heuristic* to serve the practice of functional medicine. This new model includes an explicit emphasis on principles and mechanisms that infuse meaning into the diagnosis and deepen the clinician's understanding of the often overlapping ways things go wrong. Any methodology for constructing a coherent story and an effective therapeutic plan in the context of complex chronic illness must be flexible and adaptive. Like an accordion file that compresses and expands upon demand, the amount and kind of data collected will necessarily change in accordance with the patient's situation and the clinician's time and ability to piece together the underlying threads of dysfunction.

*Heuristics are rules of thumb—ways of thinking or acting—that develop through experimentation and enable more efficient and effective processing of data.

The conventional assessment process involving the Chief Complaint, History of Present Illness, and Past Medical History sections must be expanded (Figure 2-3) to include a thorough investigation of antecedents, triggers, and mediators, and a systematic evaluation of any imbalances within the fundamental organizing systems. Personalized medical care without this expanded investigation falls short.

The Functional Medicine Matrix Model

Distilling the data from the expanded history, physical examination, and laboratory findings into a narrative story line that includes antecedents, triggers, and mediators can be challenging. Key to developing a thorough narrative is organizing the story using the Functional Medicine Matrix Model form (Figure 2-4).

The matrix form helps organize and prioritize information and also clarifies the level of present understanding, thus illuminating where further investigation is needed. For example:

- Indicators of inflammation on the matrix might lead the clinician to request tests for specific inflammatory markers (such as highly sensitive C-reactive protein, interleukin levels, and/or homocysteine).
- Essential fatty acid levels, methylation pathway abnormalities, and organic acid metabolites help determine adequacy of dietary and nutrient intakes.
- Markers of detoxification (glucuronidation and sulfation, cytochrome P450 enzyme heterogeneity) can determine functional capacity for molecular biotransformation.
- Neurotransmitters and their metabolites (vanilmandelate, homovanillate, 5-hydroxyindoleacetate, quinolinate) and hormone cascades (gonadal and adrenal) have obvious utility in exploring messenger molecule balance.
- Computed tomographic scans, magnetic resonance imaging (MRI), or plain x-rays extend the view of the patient's structural dysfunctions. The use of bone scans, dual energy x-ray absorptiometry scans, or bone resorption markers[10,11] can be useful in further exploring the web-like interactions of the matrix.
- Newer, useful technologies such as functional MRIs, single-photon emission computed tomography or positron emission tomographic scans offer more comprehensive assessment of metabolic function within organ systems.

It is the process of completing a comprehensive history and physical using the expanded functional medicine heuristic and then charting these findings on the matrix that best directs the choice of laboratory work and successful treatment.

Therapies should be chosen for their potential impact on the most significant imbalances of the particular patient. A completed matrix form facilitates review of common pathways, mechanisms, and mediators of disease and helps clinicians select points of leverage for treatment strategies. However, even with the matrix as an aid to synthesizing and prioritizing information, it can be very useful to consider the impact of each variable at five different levels.

1. Whole body interventions: Because the human organism is a complex adaptive system, with countless points of access, interventions at one level will affect points of activity in other areas as well. For example, improving the patient's sleep beneficially influences the immune response, melatonin levels, and T-cell lymphocyte levels and helps decrease oxidative stress. Exercise reduces stress, improves insulin sensitivity, and improves detoxification. Reducing stress (and/or improving stress management) reduces cortisol levels, improves sleep, improves emotional well being, and reduces the risk of heart

Chief Complaint (CC)

From the subcellular membranes to the musculoskeletal system
Initial Assessment:
– Enter data on Matrix form; look for common themes
– Review underlying mechanisms of disease
– Recapitulate patient's story
– Organ system-based diagnosis
– Functional medicine assessment: underlying mechanisms of disease; genetic and environmental influences
Treatment Plan:
– Individualized
– Dietary, lifestyle, environmental
– Nutritional, botanical, psychosocial, energetic, spiritual
– May include pharmaceuticals and/or procedures

FIGURE 2-3 Expanding the accordion file: the functional medicine assessment heuristic. (Courtesy of the Institute for Functional Medicine.)

disease. Changing the diet has myriad effects on health, from reducing inflammation to reversing coronary artery disease.

2. Organ system interventions: These interventions are used more frequently in the acute presentation of illness. Examples include splinting; draining lesions; repairing lacerations; reducing fractures, pneumothoraxes, hernias, or obstructions; or removing a stone to reestablish whole organ function. There are many interventions that improve organ function. For example, bronchodilators improve air exchange, thereby decreasing hypoxia, reducing oxidative stress, and improving metabolic function and oxygenation in a patient with reactive airway disease.
3. Metabolic or cellular interventions: Cellular health can be addressed by insuring the adequacy of macronutrients, essential amino acids, vitamins, and cofactor minerals in the diet (or, if necessary, from supplementation). An individual's metabolic enzyme polymorphisms can profoundly affect his or her nutrient requirements. For example, adding conjugated linoleic acid to the diet can alter the peroxisome proliferator activated receptor system, affect body weight, and modulate the inflammatory response.[12-14] However, in a person who is diabetic or insulin resistant, adding conjugated linoleic acid may induce hyperproinsulinemia, which is detrimental.[15,16] Altering the types and proportions of carbohydrates in the diet may increase insulin sensitivity, reduce insulin secretion, and fundamentally alter metabolism in the insulin-resistant patient. Supporting liver detoxification pathways with supplemental glycine and *N*-acetylcysteine improves the endogenous production of adequate glutathione, an essential antioxidant in the central nervous system and gastrointestinal tract.
4. Subcellular/mitochondrial interventions: There are many examples of nutrients that support mitochondrial function.[17,18]

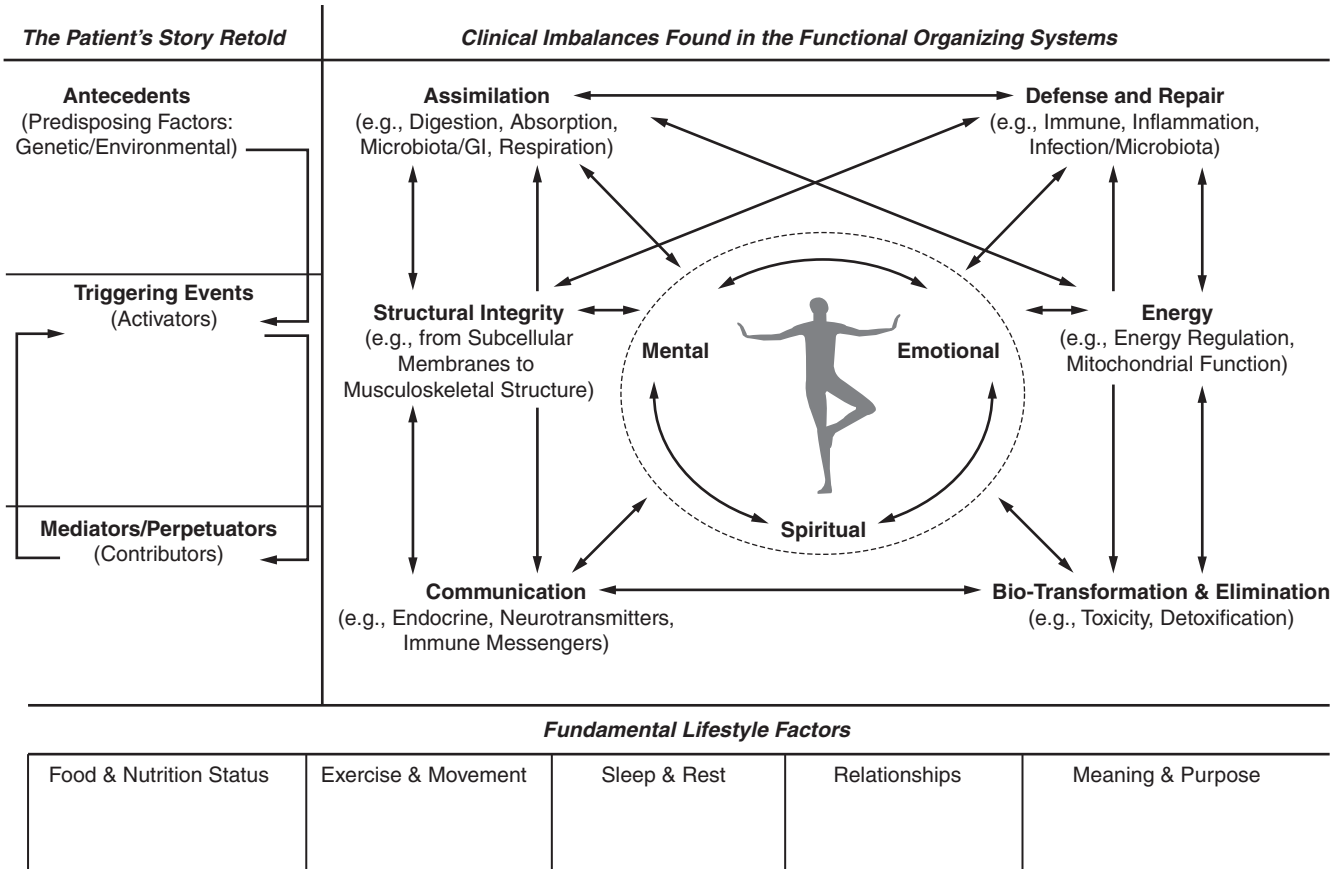

FIGURE 2-4 The functional medicine matrix model. (Courtesy of the Institute for Functional Medicine.)

Inadequate iron intake causes oxidants to leak from mitochondria, damaging mitochondrial function and mitochondrial DNA. Making sure there is sufficient iron helps alleviate this problem. Inadequate zinc intake (found in more than 10% of the U.S. population) causes oxidation and DNA damage in human cells.[18] Ensuring the adequacy of antioxidants and cofactors for the at-risk individual must be considered in each part of the matrix. Carnitine, for example, is required as a carrier for the transport of fatty acids from the cytosol into the mitochondria, improving the efficiency of β-oxidation of fatty acids and resultant adenosine triphosphate production. In patients who have lost significant weight, carnitine undernutrition can result in fatty acids undergoing ω-oxidation, a far less efficient form of metabolism.[19] Patients with low carnitine may also respond to riboflavin supplementation.[19]

5. Subcellular/gene expression interventions: Many compounds interact at the gene level to alter cellular response, thereby affecting health and healing. Any intervention that alters nuclear factor-κB entering the nucleus, binding to DNA, and activating genes that encode inflammatory modulators, such as interleukin-6 (and thus C-reactive protein), cyclooxygenase-2, interleukin-1, lipoxygenase, inducible nitric oxide synthase, tumor necrosis factor-α, or a number of adhesion molecules, will impact many disease conditions.[20,21] There are many ways to alter the environmental triggers for nuclear factor-κB, including lowering oxidative stress, altering emotional stress, and consuming adequate phytonutrients, antioxidants, alpha-lipoic acid, eicosapentaenoic acid, docosahexaenoic acid, and γ-linoleic acid.[20] Adequate vitamin A allows the appropriate interaction of vitamin A-retinoic acid with more than 370 genes.[22] Vitamin D in its most active form intercalates with a retinol protein and the DNA exon and modulates many aspects of metabolism, including cell division in both healthy and cancerous breast, colon, prostate, and skin tissue.[23] Vitamin D has key roles in controlling inflammation, calcium homeostasis, bone metabolism, cardiovascular and endocrine physiology, and healing.[23]

Experience using this model, along with improved pattern recognition skills, will often lessen the need for extensive laboratory assessments. However, there will always be certain clinical conundrums that simply cannot be assessed without objective data and, for most patients, there may be an irreducible minimum of laboratory assessments required to accumulate information. For example, in the clinical workup of autistic spectrum disorders in children, heavy metal exposure and toxicity may play an important role. Heavy metal body burden cannot be sensibly assessed without laboratory studies. In most initial workups, laboratory and imaging technologies can be reserved for those complex cases in which the initial interventions prove insufficient to the task of functional explication. When clinical acumen and educated steps in both assessments and therapeutic trials do not yield expected improvement, laboratory testing often provides rewarding information. This is frequently the context for focused genomic testing.

The Healing Partnership

No discussion of the functional medicine model would be complete without mention of the therapeutic relationship. Partnerships are formed to achieve an objective. For example, a business partnership forms to engage in commercial transactions for

financial gain; a marriage partnership forms to build a caring, supportive, home-centered environment. A healing partnership forms to heal the patient through the integrated application of both the art of medicine (insight driven) and the science of medicine (evidence driven). An effective partnership requires that trust and rapport be established. Patients must feel comfortable telling their stories and revealing intimate information and significant events.

In the twentieth century, contemporary medicine, traditionally considered a healing profession, evolved away from the role of healing the sick to that of curing disease through modern science. Research into this transition revealed that healing was traditionally associated with themes of wholeness, narrative, and spirituality. Professionals and patients alike report healing as an intensely personal, subjective experience involving a reconciliation of meaning for an individual and a perception of wholeness. The biomedical model as currently configured no longer encompasses these characteristics.

Contemporary medicine considers the wholeness of healing to be beyond its orthodoxy—the domain of the nonscientific and nonmedical.[24] We disagree. To grasp the profound importance of the healing partnership to the creation of a system of medicine adequate to the demands of the twenty-first century, an emerging body of relevant research was reviewed.[25-27] As Louise Acheson, MD, MS, Associate Editor for the *Annals of Family Practice*, articulated recently in that journal[28].

> *It is challenging to research this ineffable process called healing…. Hsu and colleagues asked focus groups of nurses, physicians, medical assistants, and randomly selected patients to define healing and describe what facilitates or impedes it.[30] The groups arrived at surprisingly convergent definitions: "Healing is a dynamic process of recovering from a trauma or illness by working toward realistic goals, restoring function, and regaining a personal sense of balance and peace." They heard from diverse participants that "healing is a journey" and "relationships are essential to healing."*

Research into the role of healing in the medical environment recently generated some thoughtful and robust investigations. Scott et al's[25] research into the healing relationship found very similar descriptions to those of Hsu et al.[29] The participants in the study[26] articulated aspects of the healing partnership as:

1. Valuing and creating a nonjudgmental emotional bond
2. Appreciating power and consciously managing clinician power in ways that would most benefit the patient
3. Abiding and displaying a commitment to caring for patients over time

Three relational outcomes result from these processes: trust, hope, and a sense of being known. Clinician competencies that facilitate these processes are self-confidence, emotional self-management, mindfulness, and knowledge.[26] In this rich soil, the healing partnership flourishes.

The characteristics of a conventional therapeutic encounter are fundamentally different from a healing partnership, and each emerges from specific emphases in training. In the therapeutic encounter, the relationship forms to assess and treat a medical problem using (usually) an organ system structure, a differential diagnosis process, and a treatment toolbox focused on pharmacology and medical procedures. The therapeutic encounter pares down the information flow between physician and patient to the minimum needed to identify the organ system domain of most probable dysfunction, followed by a sorting system search (the differential diagnosis heuristic). The purpose of this relationship is to arrive at the most probable diagnosis as quickly as possible and select an intervention based on probable efficacy. The relationship is a left-brain–guided conversation controlled by the clinician and characterized by algorithmic processing and statistical thinking.[30,31]

The functional medicine healing partnership forms with a related but broader purpose: to help the patient heal by identifying the underlying mechanisms and influences that initiated and continue to mediate the patient's illness(es). This type of relationship emphasizes a shared responsibility for identifying the causes of the patient's condition and achieving insight about enduring solutions. The healing partnership is critical to the delivery of personalized systems medicine and to manage the uncertainty (choices under risk) inherent in clinical practice. In the healing partnership, the appropriate utilization and integration of left-brain and right-brain functions are found.

In language, we have the fullest expression of the integration of left- and right-brain function. Language is so complex that the brain has to process it in different ways simultaneously—both denotatively and connotatively. For complexity and nuance to emerge in language, the left brain needs to see the trees and the right brain helps us see and understand the forest.[32,33]

The starting point for creating a healing partnership is the patient's experience. People, not diseases, can heal. Mindful integration of brain function is at the heart of a healing partnership. Some of the basic steps for establishing a healing partnership include:

1. Allowing patients to express, without interruption,[*] their story about why they have come to see you. The manner in which the patient frames the initial complaints often presages later insight into the root causes. Any interruption in this early stage of narrative moves the patient back into left-brain processing and away from insight.[34]
2. After focusing on the main complaint, encouraging the patient's narrative regarding their present illness(es). Clarifications can be elicited by further open-ended questioning (e.g., "tell me more about that"; "what else do you think might be going on?"). During this portion of the interview, there is a switching back and forth between right- and left-brain functions.
 - During this conversation, signs and symptoms of the present illness are distributed by the practitioner into the Functional Medicine Matrix Model form as previously described.
 - Analysis of the data thus collected proceeds by assessing probable underlying causes—based on evidence about common underlying mechanisms of disease—and ongoing mediators of the disease.
3. Next, conveying to the patient in the simplest terms possible that to achieve lasting solutions to the problem(s) for which he and/or she has come seeking help, a few fundamental questions must be asked and answered to understand the problem in the context of the patient's personal life. This framing of the interview process moves the endeavor from a left-brain compilation to a narrative that encourages insight—based on complex pattern recognition—about the root causes of the problem.
4. At this stage, control is shared with the patient: "Without your help, we cannot understand your medical problem in the

[*]Research focused on the therapeutic encounter has repeatedly found that clinicians interrupt the patient's flow of conversation within the first 18 seconds or less, often denying the patient an opportunity to finish. (Beckman DB, et al. The effect of physician behavior on the collection of data. Ann Intern Med. 1984;101:692-696.)

depth and breadth you deserve." Implementing this shared investigation can be facilitated by certain approaches:

a) For determining antecedent conditions, the following questions are useful:
 - When was the last time you felt well? When were you free of this problem?
 - What were the circumstances surrounding the appearance of the problem?
 - Have similar problems appeared in family members?

b) For triggers, the following question is critical:
 - What conditions, activities, or events seemed to initiate the problem? (Microbes and stressful personal events are examples, but illustrate quite different categories of triggers. Triggers by themselves are usually insufficient for disease formation, so triggers must be viewed within the context of the antecedent conditions.)

c) Mediators of the problem are influences that help perpetuate it.
 - There can be specific mediators of diseases in the patient's activities, lifestyle, and environment. Many diverse factors can affect the host's response to stressors.
 - Any of the core clinical imbalances, discussed previously and shown on the Functional Medicine Matrix Model, can transform what might have been a temporary change in homeostasis into a chronic allostatic condition.

It helps at this juncture to emphasize again that the following issues are elemental in forming a healing partnership:

- Only the patient can inform the partnership about the conditions that provided the soil from which the problem(s) under examination emerged. The patient literally owns the keys to the joint deliberation that can provide insight about the process of achieving a healing outcome.
- The professional brings experience, wisdom, tools, and techniques and works to create the context for a healing insight to emerge.
- The patient's information, input, mindful pursuit of insight, and engagement become "the horse before the cart." The cart carries the clinician—the person who guides the journey using evidence, experience, and judgment, and who contributes the potential for expert insight.

The crux of the healing partnership is an equal investment of focus by both clinician and patient. They work together to identify the right places to apply leverage for change. Patients must commit to engage both their left-brain skills and their right-brain function to inform and guide the exploration to the next steps in assessment, therapy, understanding, and insight. Clinicians must also engage both the left-brain computational skills and the right-brain pattern-recognition functions that, when used together, can generate insight about the patient's story. An overview of the functional medicine model can be seen in Figure 2-5.

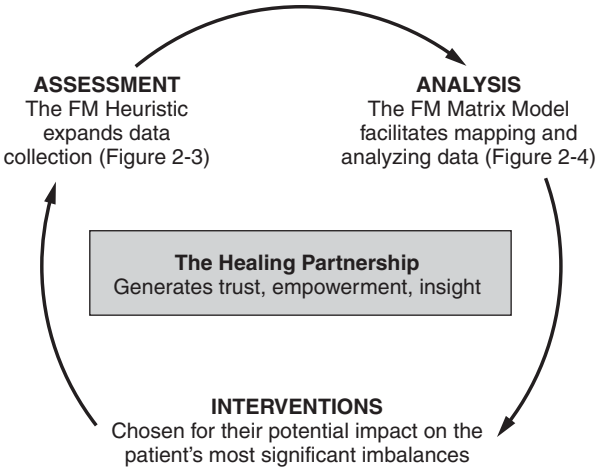

FIGURE 2-5 Overview of the functional medicine (FM) model. (Courtesy of the Institute for Functional Medicine.)

INTEGRATION OF CARE

Functional medicine explicitly recognizes that no single profession can cover all the viable therapeutic options. Interventions and practitioners will differ by training, licensure, specialty focus, and even by beliefs and ethnic heritage. However, all health care disciplines (and all medical specialties) can—to the degree allowed by their training and licensure and assuming a good background in Western medical science—use a functional medicine approach, including integrating the matrix as a basic template for organizing and coupling knowledge and data. Consequently, functional medicine can provide a common language, a flexible architecture, and a unified model to facilitate integrated and integrative care. Regardless of which discipline the clinician has been trained in, developing a network of capable, collaborative practitioners with whom to co-manage challenging patients and to whom referrals can be made for therapies outside the primary clinician's own expertise will enrich patient care and strengthen the clinician–patient relationship.

A BRIEF HISTORY OF NATUROPATHIC MEDICINE

In 1900 Benedict Lust "invented" naturopathy, a practice that combined many natural therapies and therapeutic systems under the umbrella of a comprehensive philosophy based upon the European nature cure movement that flourished in the 1800s, the vis medicatrix naturae (healing power of nature) and other vitalistic principles. As such, naturopathic medicine has deep historical roots and represents a lineage of Western natural medicine that can be traced back to the Roman, Greek, Egyptian, and Mesopotamian cultures, and conceptually, to many traditional and indigenous world medicines.

The modern naturopathic profession originated with Lust, and it grew under his tireless efforts. He crisscrossed the United States lecturing and lobbying for legislation to license naturopathy, testifying for naturopaths indicted for practicing medicine without a license, and traveling to many events and conferences to help build the profession. He also wrote extensively to foster and popularize the profession, and through his efforts, the naturopathic profession grew rapidly.[1-3] By the 1940s, naturopathic medicine had developed a number of 4-year medical schools and had achieved licensure in about one third of the United States, the District of Columbia, four Canadian provinces, and a number of other countries.[2,4]

The profession went through a period of decline, marked with internal disunity and paralleled by the rise of biomedicine and the promise of wonder drugs. By 1957, there was only one naturopathic college left. By 1975, only eight states still licensed naturopathic physicians, and by 1979, there were only six. A survey conducted in 1980 revealed that there were only about 175 naturopathic practitioners still licensed and practicing in the United States and Canada.[5] In contrast, in 1951, the number was approximately 3000.[6]

The decline of naturopathic medicine after a rapid rise was due to several factors. By the 1930s, a significant tension developed within the profession regarding naturopathic practice, as did the development of unified standards and the role of experimental, reductionist science as an element of professional development.[7,8] This tension split the profession of naturopathic physicians from within after the death of Lust in the late 1940s, at a time when the profession was subject to both significant external forces and internal leadership challenges. Many naturopathic doctors questioned the capacity for the reductionist scientific paradigm to research naturopathic medicine objectively in its full scope.[7,9,10]

This perception created mistrust of science and research. Science was also frequently used as a bludgeon against naturopathic medicine, and the biases inherent in what became the dominant paradigm of scientific reductionism made a culture of scientific progress in the profession challenging. The discovery of effective antibiotics elevated the standard medical profession to dominant and unquestioned stature by a culture that turned to mechanistic science as an unquestioned authority. The dawning of the atomic age reinforced a fundamental place for science in a society increasingly dominated by scientific discovery. In this culture, standard medicine, with its growing political and economic strength, was able to force the near elimination of naturopathic medicine through the repeal or "sunsetting" of licensure acts.[1,2,11]

In 1956, as the last doctor of naturopathy (ND) program ended (at the Western States College of Chiropractic), several doctors, including Drs. Charles Stone, W. Martin Bleything, and Frank Spaulding, created the National College of Naturopathic Medicine in Portland, OR, to keep the profession alive. However, that school was nearly invisible as the last vestige of a dying profession and rarely

attracted as many as 10 new students a year. The profession was considered dead by its historic adversaries.

The culture of America, dominated by standard medicine since the 1940s, however, began to change by the late 1960s. The promise of science and antibiotics was beginning to seem less than perfect. Chronic disease was increasing in prevalence as acute infection was less predominant, and standard medicine had no "penicillin" for chronic diseases. In the late 1970s, scholars in family medicine proposed a biopsychosocial model of care in response to a prevailing perception of a growing crisis in standard medicine.[12] The publication of Engel's "The Need for a New Medical Model" in April 1977 signaled the founding of the field of family medicine based on a holistic philosophy and paralleled a broader social movement in support of alternative health practices and environmental awareness. Elements of the culture were rebelling against plastics and cheap synthetics, seeking more natural solutions. The publication of Rachael Carson's *Silent Spring* in 1962, an indictment of chemical pesticides and environmental damage, marked a turning point in cultural thinking. In *Silent Spring,* Carson challenged the practices of agricultural scientists and the government and called for a change in the way humankind viewed the natural world.[13] New evidence of the dangers of radiation, synthetic pesticides, and herbicides, as well as environmental degradation from industrial pollution, were creating a new ethic. Organic farming, natural fibers, and other similar possibilities were starting to capture attention. A few began seeking natural alternatives in medicine. By the late 1960s and early 1970s, enrollments at the National College of Naturopathic Medicine began to reach into the 20s. The 1974 class numbered 23 students. In 1975, the National College enrolled a class of 63 students.[14] The profession was experiencing a resurgence.

In 1978, with a desire to create a college based on science-based natural medicine, Joseph E. Pizzorno, ND, LM, and his colleagues, Les Griffith, ND, LM; Bill Mitchell, ND; and Sheila Quinn created the John Bastyr College of Naturopathic Medicine in Seattle, WA. With the creation of Bastyr, named after the eminent naturopathic physician, Dr. John Bartholomew Bastyr (1912–1995), the profession entered a new phase. Not only did this new college double the profession's capacity to produce new doctors, it also firmly placed the profession on the ground of scientific research and validation. "Science-based natural medicine," coined by Dr. Pizzorno, was a major driving force behind the creation and mission of Bastyr. Both Drs. Bastyr and Pizzorno had significant influence and leadership in achieving this focus.

One of Dr. Bastyr's important legacies was to establish a foundation and a model for reconciling the perceived conflict between science and the deeply established healing practices and principles of naturopathic medicine. Kirchfeld and Boyle[3] described his landmark contribution as follows:

> *"Although naturopathic colleges in the early 1900s did include basic sciences training, it was not until Dr. John Bastyr (1912-1995) and his firm, efficient and professional leadership that science and research-based training in natural medicine was inspired to reach its fullest potential. Dr. Bastyr, whose vision was one of 'naturopathy's empirical successes documented and proven by scientific methods,' was himself the prototype of the modern naturopathic doctor, who culls the latest findings from the scientific literature, applies them in ways consistent with naturopathic principles and verifies the results with appropriate studies."*

Bastyr also saw a tremendous expansion in both allopathic and naturopathic medical knowledge, and he played a major role in making sure the best of both were integrated into naturopathic medical education.[3,15]

Bastyr met Lust on two occasions and was closely tied to the nature cure tradition of Kneipp through two influential women: his mother and his mentor, Dr. Elizabeth Peters, who studied with Father Kneipp. He effortlessly integrated the clinical theories and practices of naturopathy with the latest scientific studies and helped create a new and truly original form of modern primary clinical care within naturopathic medicine. He spent the twentieth century preparing the nature cure of the nineteenth century for entry into the twenty-first century.[1,15] Today's philosophical debates within the profession are no longer about science. They tend to center on challenges to the Nature Cure tradition. A current debate, for instance, is about the role of "green allopathy" within the profession: the tendency to use botanical medicine or nutritional supplements as a simple "green drug" or pharmaceutical replacement versus the importance of implementing the full range of healing practices derived from Nature Cure to stimulate health restoration alongside, or instead of, botanical medicine or nutritional supplements. Professional consensus appears strong that the full range of naturopathic healing practices must be retained, strengthened, and engaged in the process of education and scientific research and discovery in the twenty-first century.[16-18]

ORIGINAL PHILOSOPHY AND THEORY

Through the initial 50-year period of professional growth and development (1896–1945), naturopathic medicine had no clear and concise statement of identity. The profession was whatever Lust said it was. He defined "naturopathy" or "nature cure" as both a way of life and a concept of healing that used various natural means of treating human infirmities and disease states. The "natural means" were integrated into naturopathic medicine by Lust and others based on the emerging naturopathic theory of healing and disease etiology. The earliest therapies associated with the term involved a combination of American hygienics and Austro-Germanic nature cure and hydrotherapy. Leaders in this field included Kuhne, Lindlahr, Trall, Kellogg, Holbrook, Tilden, Graham, McFadden, Rikli, Thomson, and others who wrote foundational naturopathic medical treatises or developed naturopathic clinical theory, philosophy, and texts to enhance, agree with, and diverge from Lust's original work.[19-27]

The bulk of professional theory was found in Lust's magazines, *Herald of Health* and *The Naturopath.* These publications displayed the prodigious writings of Lust, but did not contain a comprehensive and definitive statement of either philosophy or clinical theory. Lust often stated that all natural therapies fell under the purview of naturopathy. Several texts were considered as somewhat definitive by various aspects of the profession at different times. These texts included the seven-volume *Natural Therapeutics* by Henry Lindlahr, MD, which was published in the early 1900s. Lindlahr's *Nature Cure* (1913) was considered a seminal work in naturopathic theory, laying the groundwork for a systematic approach to naturopathic treatment and diagnosis. Lindlahr ultimately presented the most coherent naturopathic theory extant, summarized in his *Catechism of Naturopathy,* which presented a five-part therapeutic progression:

1. "Return to Nature"—attend to the basics of diet, dress, exercise, rest, etc.
2. Elementary remedies—water, air, light, electricity
3. Chemical remedies—botanicals, homeopathy, etc.
4. Mechanical remedies—manipulations, massage, etc.
5. Mental/spiritual remedies—prayer, positive thinking, doing good works, etc.[28]

In the 1950s Spitler wrote *Basic Naturopathy, a Textbook*,[9] and Wendel wrote *Standardized Naturopathy.*[10] These texts presented somewhat different approaches; Spitler's text emphasized theory and philosophy, whereas Wendel's text was written, as evidenced by the title, to emphasize the standard naturopathic practices of the day, with an eye toward regulatory practice. In contrast, Kuts-Cheraux's *Naturopathic Materia Medica*, written in the 1950s, was produced to satisfy a statutory demand by the Arizona legislature, but persisted as one of the few extant guides of that era. Practitioners relied on a number of earlier texts, many of which arose from the German hydrotherapy practitioners[29-34] or the Eclectic school of medicine (a refinement and expansion of the earlier "Thomsonian" system of medicine)[35-39] and predated the formal American naturopathic profession (1900). However, by the late 1950s, publications diminished. The profession was generally considered on its last gasp, an anachronism of the pre-antibiotic era.

During the process of winning licensure, naturopathic medicine was defined formally by the various licensure statutes, but these definitions were legal and scope-of-practice definitions, often in conflict with each other, reflecting different standards of practice in different jurisdictions. In 1965, the U.S. Department of Labor's *Dictionary of Occupational Titles*[40] presented the most formal and widespread definition. The definition was not without controversy. as it reflected one of the internally competing views of the profession, primarily, the nature cure perspective:

> *"Diagnoses, treats and cares for patients using a system of practice that bases treatment of physiological function and abnormal conditions on natural laws governing the human body. Utilizes physiological, psychological and mechanical methods such as air, water, light, heat, earth, phytotherapy, food and herbs therapy, psychotherapy, electrotherapy, physiotherapy, minor and orificial therapy, mechanotherapy, naturopathic corrections and manipulations, and natural methods or modalities together with natural medicines, natural processed food and herbs and natural remedies. Excludes major surgery, therapeutic use of x-ray and radium, and the use of drugs, except those assimilable substances containing elements or compounds which are components of body tissues and physiologically compatible to body processes for the maintenance of life."*[40]

This definition did not list drugs or surgery within the scope of modalities available to the profession. It defined the profession by therapeutic modality and was more limited than most of the statutes under which naturopathic physicians practiced,[41] even in 1975, when there were only eight licensing authorities still active.

MODERN NATUROPATHIC CLINICAL THEORY: THE PROCESS OF DEVELOPMENT

> *"Medical philosophy comprises the underlying premises on which a health care system is based. Once a system is acknowledged, it is subject to debate. In Naturopathic medicine, the philosophical debates are a valuable, ongoing process which helps the understanding of health and disease evolve in an orderly and truth-revealing fashion."*
>
> ***—Randall Bradley, ND[42]***

After the profession's decline in the 1950s and 1960s, a rebirth was experienced, more grounded in medical sciences and fueled by a young generation with few teachers. The profession's roots were neglected out of ignorance, for the most part, along with a youthful arrogance. By the early 1980s, it was apparent that attempts to regenerate the progress made by Lust would require the creation of a unified professional organization and all which that entailed: accreditation for schools, national standards in education and licensure, clinical research, and the articulation of a coherent definition of the profession for legislative purposes, as well as for its own internal development. These accomplishments would be necessary to be able to demonstrate the uniqueness and validity of the profession, guide its educational process, and justify its status as a separate and distinct medical profession.

In 1987, the newly formed (1985) American Association of Naturopathic Physicians (AANP) began this task under the leadership of James Sensenig, ND (president) and Cathy Rogers, ND (vice president), appointing a committee to head the creation of a new definition of naturopathic medicine. The "Select Committee on the Definition of Naturopathic Medicine" succeeded in a 3-year project that culminated in the unanimous adoption by AANP's House of Delegates (HOD) of a comprehensive, consensus definition of naturopathic medicine in 1989 at the annual convention held at Rippling River, OR.[43-45] The unique aspect of this definition was its basis in definitive principles, rather than therapeutic modalities, as the defining characteristics of the profession. In passing this resolution, the HOD also asserted that the principles would continue to evolve with the progress of knowledge and should be formally reexamined by the profession as needed, perhaps every 5 years.[43-48]

In September 1996, the AANP HOD passed a resolution to review three proposed principles of practice that had been recommended as additions to the AANP definition of naturopathic medicine originally passed by the HOD in 1989. These three new proposed principles were rejected, and the AANP HOD reconfirmed the 1989 AANP definition unanimously in 2000. The results of a profession-wide survey conducted from 1996 to 1998 on these three new proposed principles demonstrated that although there was lively input, the profession agreed strongly that the original definition was accurate and should remain intact. The HOD recommended that the discussion be moved to the academic community involved in clinical theory, research, and practice for pursuit through scholarly dialogue.[49-53] This formed the basis for further efforts to articulate a clinical theory. AANP members stated in 1987–1989 during the definition process: "These principles are the skeleton, the core of naturopathic theory. There will be more growth from this foundation."[45] By 1997, this growth in modern clinical theory was evident.

The first statement of such a theory was published in the AANP's *Journal of Naturopathic Medicine* in 1997 in an article titled "The Process of Healing, a Unifying Theory of Naturopathic Medicine."[54] This article contained three fundamental concepts that were presented as an organizing theory for the many therapeutic systems and modalities used within the profession and were based on the principles articulated in the consensus AANP definition of naturopathic medicine. The first of these was the characterization of disease as a process rather than a pathologic entity. The second was the focus on the determinants of health rather than on pathology. The third was the concept of a therapeutic hierarchy.

This article also signaled the emergence of a growing dialogue among physicians, faculty, leaders, and scholars of naturopathic philosophy concerning theory in naturopathic medicine. The hope and dialogue sparked by this article was the natural next step of a profession redefining itself both in the light of today's advances in health care and with respect to the foundations of philosophy at the traditional heart of naturopathic medicine. This dialogue naturally followed the discussions of the definition

process and created a vehicle for emerging models and concepts to be built on the bones of the principles. The essence and inherent concepts of traditional naturopathic philosophy were carried in the hearts and minds of a new generation of naturopathic physicians into the twenty-first century—these modern naturopathic students and naturopathic physicians began to gather to articulate, redefine, and reunify the heart of the medicine.

This new dialogue was formally launched in 1996, when the AANP Convention opened with the plenary session: "Towards a Unifying Theory of Naturopathic Medicine" with four naturopathic physicians presenting facets of emerging modern naturopathic theory. The session closed with an open microphone. The impassioned and powerful comments of the naturopathic profession throughout the United States and Canada engaged in the vital process of deepening and clarifying its unifying theory. Dr. Zeff presented "The Process of Healing: The Hierarchy of Therapeutics"; Dr. Mitchell presented "The Physics of Adjacency, Intention, Naturopathic Medicine, and Gaia"; Dr. Sensenig presented "Back to the Future: Reintroducing Vitalism as a New Paradigm"; and Dr. Snider announced the Integration Project, inviting the profession to engage in it by "sharing a beautiful and inspiring anguish—the labor pains of naturopathic theory in the twenty-first century. We know what we have done, and we know there is much more…The foundation is laid. We are ready now for development and integration."[55]

Days later, in September 1996, the Consortium of Naturopathic Medical Colleges (now the American Association of Naturopathic Medical Colleges [AANMC]) formally adopted and launched the Integration Project, an initiative to integrate naturopathic theory and philosophy throughout all divisions of all naturopathic college curricula, from basic sciences to clinical training. A key element of the project engaged the further development and refinement of naturopathic theory. The project was co-chaired by Drs. Snider and Zeff from 1996 to 2003. Steering members from all North American naturopathic colleges participated and contributed.[45] Methods included professional and scholarly research, expert teams, symposiums, and training. The result was the fostering of systematic inquiry among academicians, clinicians, and researchers concerning the underlying theory of naturopathic medicine, bringing the fruits of this work and inquiry into the classroom and into scientific discussion.[56]

The Integration Project sustained both formal and informal dialogue since its inception in 1996, which continues today. The work has engaged faculty and scholars of naturopathic philosophy in the United States, Canada, and Australia. It has also engaged institutional leaders and practicing doctors and faculty in all areas of the profession. Why? Naturopathic philosophy is deeply felt as the "commons" of naturopathic medicine: a place where the profession meets—one that is owned by all naturopathic physicians—that reflects, holds, and deepens the heart of naturopathic medicine. Naturopathic philosophy is the foundation and heart of naturopathic medicine. It remains valid by evolving with the progress of knowledge, the progress of science, and the progress of the human spirit. It is for this reason medicine is seen as an art as well as a science. Because naturopathic philosophy engages the intuitively felt mission of nature doctors, it is vital that the profession periodically gathers to renew and revitalize progress regarding its unifying foundations.

The Integration Project sparked a wide range of activities in all six ND colleges, resulting in all-college retreats to share tools, retreats for training of non-ND faculty in naturopathic philosophy, integration of a basic sciences curriculum, expert teams revision of core competencies across departments ranging from nutrition to case management and counseling, development of clinical tools and seminars for clinic faculty, creation of new courses, and the integration of important research questions derived from naturopathic philosophy into research studies and initiatives.[57] The latest effort is the Foundations of Naturopathic Medicine Project (textbook and symposia series, www.foundationsproject.com) and its development and presentation of the educational module on Emunctorology, an essentially naturopathic science, during 2009 and 2010. This is a joint effort of faculty from several of our schools, led by Drs. Thom Kruzel and Stephen Myers.

North American core competencies for naturopathic philosophy and clinical theory were developed by faculty representing all accredited ND colleges in a landmark AANMC retreat in 2000. The AANMC's Dean's Council formally adopted these competencies in 2000 and recommended that they be integrated throughout curricula in all ND colleges. These national core competencies included the process of healing theory, Lindlahr's model, and the hierarchy of therapeutics (the therapeutic order).[58,59]

Finally, many meetings with scholars and teachers of naturopathic theory and other faculty and leaders—formal and informal—resulted in the further development and refinement of the hierarchy of therapeutics developed by Dr. Zeff in 1997.

Drs. Snider and Zeff and naturopathic theory faculty worked closely with other naturopathic faculty from AANMC colleges in a series of revisions. Drs. Snider and Zeff collaborated in 1998 to develop the hierarchy of therapeutics into the therapeutic order. The therapeutic order was subsequently explored and refined through a series of faculty retreats and meetings, as well as through experience with students and through student feedback. A key finding of the clinical faculty at Bastyr University was the emphasis on the principle "holism: treat the whole person" and respect for the patient's own unique healing order and his or her values as a context for applying the therapeutic order to clinical decision making.[60] The therapeutic order, or hierarchy of healing, is now incorporated into ND college curricula throughout the United States, Canada, Australia, and New Zealand. For example, an important international outgrowth of the profession's development of theory is the adoption of the unified *"Working Definition of Naturopathic Nutrition"* in June 2003 by the Australian naturopathic profession (Box 3-1). The 3-year project, fostered by Dr. Stephen Myers, brought together nutrition faculty from naturopathic medicine colleges throughout Australia. The project was co-hosted by the Naturopathy and Nutrition panel, an independent group of naturopaths and nutrition educators whose mission is to foster and support the development of the science, teaching, and practice of naturopathic nutrition, and the School of Natural and Complementary Medicine at Southern Cross University. The definition evolved over two retreats attended by more than 40 faculty members involved in teaching nutrition as part of a naturopathic medicine education. It commenced as a general agreement within the group that there was a real and distinct difference between conventional nutritional concepts and naturopathic nutritional theory. General agreement was that the distinction between the two had to date been poorly defined and had been the source of dissonance between the naturopathic and science faculty within the colleges. The obvious next step was to define that difference to ensure that nutrition curriculum within naturopathic medicine colleges reflected the core elements of naturopathic nutrition. At the second retreat held in June 2003, the working definition was adopted with a recommendation that it be widely circulated within the naturopathic medicine profession to commence a dialogue aimed at both appropriate revision and broad adoption. This process created a much-needed consensus definition on naturopathic nutrition. This definition is based on the AANP defining principles and incorporates the therapeutic order theory.

BOX 3-1 **Working Definition of Naturopathic Nutrition**

Preamble

Naturopathic medicine is a distinct system of primary health care—an art, science, philosophy and practice of diagnosis, as well as treatment and prevention of illness. Naturopathic medicine is distinguished by the principles that underlie and determine its practice. These principles include the healing power of nature (vis medicatrix naturae), identification and treatment of the causes (tolle causam), the promise to first do no harm (primum non nocere), doctor as teacher (docere), treatment of the whole person, and emphasis on prevention. These principles give rise to a practice that emphasizes the individual and empowers him or her to greater responsibility in personal health care and maintenance.

Definition

Naturopathic nutrition is the practice of nutrition in the context of naturopathic medicine.

Naturopathic nutrition integrates both scientific nutrition and the principles of naturopathic medicine into a distinct approach to nutritional practice.

Core components of naturopathic nutrition are:

- A respect for the traditional and empirical naturopathic approach to nutritional knowledge
- The value of food as medicine
- An understanding that whole foods are greater than the sum of their parts and recognition that they have vitality (properties beyond physiochemical constituents)
- Individuals have unique interactions with their nutritional environments

Practice

In the context of the definition, and with respect to the therapeutic order, the practice of naturopathic nutrition may include the appropriate use of the following:

- Behavioral and lifestyle counseling
- Diet therapy (including health maintenance, therapeutic diets, and dietary modification)
- Food selection, preparation, and medicinal cooking
- Therapeutic application of foods with specific functions
- Traditional approaches to detoxification
- Therapeutic fasting strategies
- Nutritional supplementation

Data from Snider P, Payne S. Making naturopathic curriculum more naturopathic: agendas, minutes, 1999-2001. Clinic faculty task force on integration. Faculty development retreat, Bastyr University, 1999.

A THEORY OF NATUROPATHIC MEDICINE

Standard medicine, or biomedicine, has a simple and elegant paradigm. Simply stated, it is "the diagnosis and treatment of disease." In practice, this statement contains several assumptions. One assumption is that illness can be understood in terms of discrete diseases (i.e., human illnesses can be divided into identifiable entities, such as measles or specific forms of cancer, etc.). The next assumption is that "cure" is the elimination of the disease entity. The third assumption is that this is accomplished by the evidence-based application of pharmaceuticals, surgeries, or similar treatments to eliminate, palliate, or suppress the entity and its symptomatic expressions. These are so obvious that they are not commonly considered. They form the background thinking in medical decision making: identify and treat the disease.

The elegance of this model, and the science behind it, has taken medicine to its highest point in history as a reliable vehicle to ease human illness, and its application has saved countless lives. The understanding of the physician, at least about the nature of pathology, has never been as complete. However, illness has a near-infinite capacity to baffle the physician. New diseases arise, such as human immunodeficiency virus/acquired immune deficiency syndrome, and shifts occur in disease focus, such as the shift between 1900 and 2000 from acute infection to chronic illness as the predominant cause of death.[61]

Beyond these obvious changes, even with the current depth of understanding, the standard medical world often lacks the ability to effectively understand and cure chronic disease, and treatment tends to become a task of the management of symptoms and the attempt to reduce long-term damage and other consequences, rather than actual cure of the illness. So, even representing an apex of human achievement as it does, modern medicine is not without its weaknesses. Its greatest weakness is probably this inability to cure chronic illness as easily as it once cured pneumonia with penicillin or tuberculosis with streptomycin. Compounding the problem is the growing prevalence of antibiotic-resistant infections.[62,63] Part of the reason for the failures within modern medical science is its mechanistic basis. Breaking the body down to its constituent parts has led to a fundamental ignorance of and disrespect for the wholeness of the individual, the natural laws of physiology governing health and healing, and particularly for all things spiritual (the transpersonal domains). Inherent in the dictum—diagnose and treat the disease—is the general neglect of the larger understanding that disease is a process conducted by and within an intelligent organism that is constantly attempting to heal itself, with disease manifestations often expressions of this self-healing endeavor. As noted by Pizzorno et al,[64] this intelligent organism strives for optimal function and health. Human beings "…are natural organisms, our genomes developed and expressed in the natural world. The patterns and processes inherent in nature are inherent in us. We exist as a part of complex patterns of matter, energy, and spirit. Nature doctors have observed the natural processes of these patterns in health and disease and determined that there is an inherent drive toward health that lives within the patterns and processes of nature."

The uniqueness of naturopathic medicine is not in its therapeutic modalities or the "natural" alternatives to the drugs and surgeries of standard medicine. It is in the clinical theory that governs the selection and application of these modalities, captured in the unifying definition adopted in 1989 and expressed more specifically in the continuing articulation of clinical theory. That is, it is the way the naturopathic physician thinks about illness and healing.

The first element of this theory is based upon the first defining principle: vis medicatrix naturae. It is based on the understanding that disease can be seen as a process, as well as an entity. One can analyze the process of illness and derive some understanding. However, to do this, one needs to examine the assumptions underlying this concept. The governing assumptions of standard medicine are principally that diseases are entities, and that drugs and surgery can eliminate these entities from the suffering person. These are not the governing assumptions of naturopathic medicine.

ILLNESS AND HEALING AS PROCESS

Naturopathic medicine can be characterized by a different model than "identify and treat the disease." "The restoration of health" would be a better characterization. Naturopathic physicians adopted the following elegantly brief definition of naturopathic

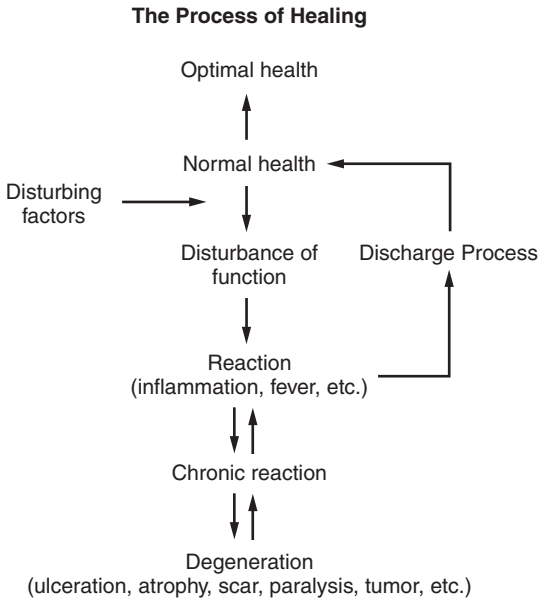

FIGURE 3-1 The process of healing (used by permission Jared L. Zeff, ND).

medicine in 1989 in an AANP position paper: "Naturopathic physicians treat disease by restoring health."[44] Immediately a significant difference is made clear: standard medicine is disease based; naturopathic medicine is health based. Although naturopathic medical students study pathology with the same intensity and depth as standard medical students, as well as its concomitant diagnoses, the naturopathic medical student learns to apply that information in a different context. In standard medicine, pathology and diagnosis are the basis for the discernment of the disease "entity" that afflicts the patient, the first of the two steps of identifying and destroying the entity of affliction. In naturopathic medicine, however, disease is seen much more as a process than as an entity. Rather than viewing the ill patient as experiencing a "disease," the naturopathic physician views the ill person as functioning within a process of disturbance and recovery, in the context of nature and natural systems. Various factors disturb normal health. If the physician can identify these disturbances and moderate them (or at least some of them), the illness and its effects abate, at least to some extent, if not totally. As disturbances are removed, the body can improve in function, and in doing so, health naturally improves. The natural tendency of the body is to maintain itself in as normal a state of health as is possible—this is the basis of homeostatic principles.[65] The role of the physician facilitates this self-healing process.

The obvious first task of the naturopathic physician, therefore, is to determine what is disturbing the health so that these causative elements may be ameliorated. Disease is the process whereby the intelligent body reacts to disturbing elements. It employs such processes as inflammation and fever to help restore its health. In general, one can graph this process simply, as in Figure 3-1.

The Naturopathic Model in Acute Illness

One can see "illness-as-process" most easily in the common cold. Within standard medical understanding, the common cold is caused by a virus, from among a family of pathologic viruses, which can infect a person. The immune system responds, developing appropriate antibodies, which eventually neutralize the virus. There is no "cure" yet discovered, except time. Medications are used to ameliorate the symptomatic experience: aspirin or acetaminophen for fever, antihistamines to dry the mucus discharge, etc. These measures are not cures; they reduce the symptomatic expression of the "cold" but often lengthen the process. In naturopathic medicine, the cold is seen not as a disease entity, but as part of a fundamental process whereby the body restores itself to health.

If the virus were the sole cause of the common cold, then everyone who came into contact with sufficient dose of the virus would get the cold. Obviously, this does not happen. Susceptibility factors include immune competence, fatigue, vitality, genetics, and other host factors.[66] The virus enters a milieu in which all these factors affect the process. Once the virus enters the system, and if it overcomes resistance factors (Box 3-2), one begins to see disturbance of function, as illustrated in Figure 3-1. One does not feel quite right. One may begin to get a sore throat, the first inflammatory reaction, occurring at the point of entry of the virus into the body. The immune factors described may overcome the virus at this point, may be insufficient, or may be suppressed. All of this is mutable to some extent and is affected by host factors, such as nutritional status and fatigue, and can be influenced by taking immune tonics, vitamin C, and other supplements.

To the individual with the condition, the "cold" may proceed into a general state of fatigue and inflammation, possibly fever followed by mucus discharge, cough, and other symptoms, as the body processes and responds to the virus and its effects; eventually the body overcomes it and eliminates the results.

In the naturopathic model, the virus is not understood so much to be a separate disease entity, but a general and fundamental process of disturbance and recovery within the living body. It is a method whereby the body restores itself after a sufficient amount of disturbance accumulates within the system. This is why the cold has no "cure." It is the cure for what ails the body. In the naturopathic model of health, it is the support of this "adaptive response"—the restoration of balance that is the central point—through which the process is the "cure" (Box 3-3).

BOX 3-2 Scientific Considerations: The Immune Response and Resistance Factors

Once inside the body, the rhinovirus binds to cellular receptors (primarily the intercellular adhesion molecule-1 [ICAM-1]) or to the low-density lipoprotein (LDL) receptor. The viral particles are then internalized and begin to take over the cellular machinery to produce intact virions.[66,67] At this stage, the body can sometimes mount an adequate defense via cell-mediated immunity to overcome the viral incursion. If we have been previously exposed to the virus, the body's humoral immune response will rapidly produce antibodies to the viral protein, which can also lead to eradication of the microbe. These two immune responses explain why some individuals may develop the full condition, whereas others will shake off the exposure within a few hours. If the viral load overcomes the body's innate defenses, the virus replicates unabated. In the process of replication, the virus not only disrupts the cellular mechanisms, but damages them as well by infecting the surface epithelium, as well as the macrophages[68] and fibroblasts.[69] Naturopathic physicians are interested in the factors that lead to greater immune competence and health restoration through the process of healing and the health practices that support it. French physiologist Claude Bernard (1813–1878) said that the inner terrain or "milieu interieur" was the cause of disease, and not the microbes; this concept underpins the naturopathic approach.

BOX 3-3 Scientific Considerations: Consequences of Suppressing the Body's Response

Current research shows that future pathologies may be linked to "suppression" of early rhinovirus infection. These include childhood asthma, adult asthma, and chronic obstructive pulmonary disease (COPD).[70,71] Individuals with asthma are known to have subtle deficiencies in production of type I and type III interferon (IFN),[72,73] indicating that for some asthma patients, early exposure to the rhinovirus predisposes them to asthma, and that the suppression of the normal response may be critical in the future development of asthma. With these effects in mind, the naturopathic physician does not look solely at the virus as a pathogenic entity, but also seeks to determine how the patient responds to the virus, thereby determining the most reasonable approach to aiding the patient's natural responses and moderating the patient's long-term health strategies. Suppression of the body's natural responses is avoided. The long-term use of corticosteroids is a prime example of suppression and its consequences.[74,75]

BOX 3-4 Scientific Considerations: The Role of Environment in Chronic Illness

Environmental and lifestyle disturbances are a profound driver in the naturopathic model of health. The scientific evidence is now irrefutable that the national and global burden of chronic disease is highly dependent on modifiable behavioral factors. In a recent study of the causes of death, it was found that tobacco, poor diet and lack of physical activity, alcohol and drug use, toxic agents, and vehicular and firearm incidents were the leading actual causes of death.[79] Other factors included frank malnutrition (as opposed to poor nutrition), unsafe sexual practices, and poor sanitation.[80,81] It has been definitively shown, for example, that diet and lifestyle changes can prevent some forms of diabetes[82,83] and other chronic diseases[84,85] that are leading causes of death in the United States.[79,82,83]

The Naturopathic Model in Chronic Illness

Chronic illness arises, in general, when any or all of three factors occur:

1. The disturbing factors persist, such as a chronically improper diet, which continues to burden the body cumulatively, as the digestive processes slowly weaken under the stress of the improper or inadequate diet.
2. The reactive potential is blocked or suppressed, usually by drugs, which interfere with the capacity of the body to process and remove its disturbances.
3. The vitality of the system is insufficient, or has become too overwhelmed, to mount a significant and sufficient reaction.

As these three factors prevent a sufficient reactive purge of disturbances, the body slides into a chronic, weakened reactive state with possible episodes of intermittent reaction, and is perceived to be in a persistent chronic illness. Ultimately, as function is sufficiently disturbed, structures or functions are damaged, and chronic inflammation becomes ulceration or scar tissue formation. In terms of the allostatic model, the balance has been disrupted, and there is no more adaptive potential. Atrophy, paralysis, or even tumor formation[76–78] may occur. All of this is the body manifestly doing the best it can for itself in the presence of persistent disturbing factors and with respect to the limitations and range of vitality influenced by the constitution, psycho-emotional/spiritual state, genotype of the person, and his or her surrounding environment (Boxes 3-4 and 3-5).

BOX 3-5 Scientific Considerations: Chronic Illness and the Adaptive Response

Regarding the responses of an overwhelmed or chronically disturbed organism, it has been argued recently that the anemia of chronic disease is an adaptive biological response rather than a harmful disorder and is associated with a number of chronic states.[86] Citing a number of studies, it was also argued that it was the treatment of the anemia of chronic disease among critically ill patients and those with renal failure and cancer (e.g., breast cancer and head and neck cancers) that was associated with the greater mortality. The U.S. Food and Drug Administration issued a warning against the use of erythropoiesis-stimulating agents in those cancer patients not undergoing chemotherapy or radiation therapy.[87]

States where the normal compensatory mechanisms become overwhelmed or suppressed (reducing the reactive potential of the body) include states of chronic oxidative stress[88] and inflammatory processes.[89,90] It is not, however, solely a matter of an overwhelmed or chronically disturbed organism that is critical to the process of disease progression. Adaptive responses are also of vital importance to the development of chronic disease. Research has shown that these evolutionarily preserved adaptive mechanisms of physical activity, insulin sensitivity, and fat storage are essential in the prevention of chronic disease states.[84,85] In the development of type 2 diabetes, for example, there is increasing evidence that it is the individual's maladaptation to lack of physical activity that appears to lead to decreased insulin sensitivity and increased fat storage, which can then lead to a plethora of chronic diseases, many characterized by states of chronic inflammation[91] and oxidative stress. Continuing basic and clinical studies indicate that many of the processes currently regarded in mainstream medicine as harmful have been evolutionarily retained to provide an adaptive advantage.[92,93] The Harvard Health Letter recently published an article describing inflammation as part of the "Unifying Theory of Disease"[94] giving support to the argument that inflammation is crucial in both health and disease and that chronic diseases arise when the inflammatory process occurs without appropriate control. The allostatic model also provides a theoretical basis for naturopathic clinical theory. The allostatic model describes the process of achieving stability (homeostasis) through changes in the homeostatic "set points" or control boundaries.[95-98] Homeostasis, the maintenance of stability in biochemical and physiologic processes, is essential for life—and allostasis, the "re-setting" of the homeostatic "set points", is essential for the maintenance of homeostasis. As it develops through the various iterations of researchers and clinicians, the model emphasizes the need to look beyond the current linear-reductionist model of disease and toward a more wholistic and balanced approach to disease conditions.

The adaptive response of the organism to insult or frank structural damage is a concept that also has support outside naturopathic medicine. For example, Schnaper et al[99] described a conceptual framework for progressive kidney disease where the initial disease develops through an injury of some nature that provokes a cellular response as an adaptation to the original injury. Where this cellular response is effective, no progressive kidney disease may ensue. If, however, there is a maladaptation, these attempts at self-repair may lead to progressive loss of nephrons and chronic kidney disease.

Reversal of this overwhelmed condition is rarely accomplished by medicating the pathologic state. This often results in the control of symptoms but with the persistence of the illness, while ideally controlling its more dangerous aspects using higher force interventions such as pharmaceutical drugs and surgical intervention. Reversal is more likely accomplished by identifying and ameliorating the disturbance, and as necessary, strengthening or

supporting the reactive potential. The first step in this process is to identify and reduce disturbing factors.

THE DETERMINANTS OF HEALTH

To reduce the disturbance, one must identify the disturbance. In standard medicine, the first step is to identify the pathology, which is then treated. In naturopathic medicine, one must come to understand what is disturbing the health. To do this, the physician needs to understand what determines health in the first place. The physician can then evaluate the patient in these terms and come to understand what is disturbing the natural state of health. Such a list could be created by any doctor, certainly any naturopathic physician. The authors propose using the list in Box 3-6.

Some of these determinants have been discussed—those modifiable behavioral factors such as drug and alcohol use, poor diet or frank malnutrition, lack of physical exercise, environmental and socioeconomic factors, and unsafe sexual practices.[79-81,100] (Box 3-7). Many of these behavioral factors have major psychological and spiritual components, and the effect can be increased stress on both the individual and the family, with all its attendant consequences.[100-102] The naturopathic physician evaluates the patient with these areas in mind, looking for aspects of disturbance, first in the spirit, and most generally in diet, digestion, and stress in its various aspects. In this evaluation, the naturopathic physician brings to bear a body of knowledge somewhat unique to naturopathic medicine to evaluate not solely in terms of pathologic entity, but in terms of normal function and subclinical functional disturbance (Box 3-8). By locating areas of abnormal function or disturbance, the naturopathic physician acts or recommends ways to ameliorate the disturbance.

As disturbing factors or insults to the system are reduced, the natural tendency of the system is to improve and optimize its function, directing the system back toward normalcy, or homeostasis. In more conventional medical terms, this is one of the fundamental concepts of the allostatic model.[95-98,101] In naturopathic thinking, this is the removal of the obstacles to cure, which allows the emerging action of the vis medicatrix naturae, the vital force, the healing power of nature. This is the first step in the hierarchy of healing and what naturopathic physicians may call the overarching model in the clinical theory (the process of healing) of naturopathic medicine: the therapeutic order. This process can be seen in the naturopathic model of healing in Figure 3-1.

THERAPEUTIC ORDER

The therapeutic order is a natural hierarchy of therapeutic intervention based on, or dictated by, observations of the nature of the healing process from ancient times through the present.[112] "Therapeutic orders" also exist in traditional Chinese, Tibetan, Ayurvedic, and Unani medicine theories. It is a natural ordering of the modalities of naturopathic medicine and their application. The concept is somewhat plastic, in that one must evaluate the unique needs, and even the unique healing requirements, of the specific patient or situation.[113] However, in general, the nature of healing dictates a general approach to treatment. In general, this order is listed in Box 3-9.

An analogy for the therapeutic order in Australian standard medicine is what is called the "softer option" model of patient care.[118] This model recognizes that, given a choice, the patient will generally choose the softer option, provided that this does not limit a harder option, if the softer option fails. By way of example, given a choice between an antibiotic and amputation for a minor cut finger, most people would choose the softer option. Expanding this range of choice to an herbal cream, antiseptic (herbal or nonherbal) and a Band-Aid, an antibiotic, or amputation, we develop a therapeutic order ranging from the softest option (the least force) to the hardest option (the higher force intervention). The therapeutic order can be seen as a progression of therapeutic interventions that begin with this "softer option."

BOX 3-6 **Naturopathic Medicine Determinants of Health**
Factors That Influence Health

Inborn Determinants
Genetic make-up (genotype)
Intrauterine/congenital factors
 Intrauterine influences: maternal nutrition, health, & lifestyle
 Maternal exposures: drugs, toxins, illnesses, viruses, psycho-emotional
Constitution: determines susceptibility

Disturbances/Disturbing Factors
Illnesses: Pathobiography
Medical Interventions (or lack of)
Physical and emotional exposures, stresses and trauma
Toxic and harmful substances
Trauma (physical/emotional)
Toxemia
Addictions
Environmental disturbances, stress: environmental, physical, emotional

How We Live - Hygienic, Lifestyle, Psycho-emotional, Spiritual, Socioeconomic & Environmental Factors

BOX 3-7 Scientific Considerations: Subclinical Inflammation and Chronic Illness

It is becoming increasingly evident that many chronic diseases may have a long subclinical phase, most involving the inflammatory process. As mentioned, a chronic, subclinical inflammatory state has been linked to a number of disorders, including insulin resistance,[104] obesity,[105] vascular disease,[106-109] hypertension,[110] and aging.[111]

BOX 3-8 Scientific Considerations: Determinants of Health within Public and Community Health Concerns

There exists increasing consensus that Crohn's disease and ulcerative colitis result from the combined effects of four important factors, none of which are individually sufficient to cause the disease. These four factors are the global changes in the environment, alterations in the microbiome of the intestine, multiple genetic factors, and aberrations or maladaptations in both the innate and adaptive immune systems.[114-117] These four factors, considered to be vital to the development and the increased rates of irritable bowel disease, are quite similar to the Determinant of Health described in Box 3-6. This serves as a further example of the growing appreciation for the similarities (with important differences) between naturopathic medicine and public and community health.

Acute and Chronic Concerns

As discussed previously, there is an inherent drive toward health that is observable within the patterns and processes of nature. The drive is not perfect. There are times when unguided, unassisted, or unstopped, the drive goes astray, causing preventable harm or even death in patients; the constructive healing intention[119] becomes destructive pathology. The ND is trained to know, respect, and work with this drive in both acute and chronic illness, using the therapeutic order, and to know when to wait or do nothing, act preventively, assist, amplify, palliate, intervene, manipulate, control, or even suppress using the principle of the least force.[120] Acute and chronic concerns are both addressed and managed using the therapeutic order.[121] Acute concerns are addressed first to avoid further damage, risk, or harm to the patient. The point of entry for assessment and therapy is dependent on each patient's need for effective, safe care, healing, and prevention of suffering and degeneration.[64,121]

Naturopathic physicians avoid suppression of symptoms in acute circumstances unless necessary for patients' well-being and safety. Instead, wherever possible, therapies for acute concerns use the least force (minimizing toxic side effects, suppression of natural functions, and physiologic burdens) available to intervene effectively, healing or palliating as needed. The full range of modalities from nutrition to homeopathy, botanical and physical medicine, hydrotherapy, counseling, prescriptive medication, and surgery are available to the patient as the naturopathic physician works to apply the least force in providing effective preventive, acute, and chronic care.[121]

Establish the Conditions for Health

Identify and Remove Disturbing Factors

If one understands health to be the natural state and "disturbance" the original culprit, then identifying and reducing disturbance is the obvious first step, unless there is immediate danger to life or limb, in which case acting to reduce suffering and preserve life or limb is paramount. In most chronic disease, neither is immediately threatened. This understanding dictates the primary treatment goal the physician must attend to: the identification and amelioration of those factors disturbing health, especially factors that most disturb health (inappropriate diet, excessive stress, and spiritual disharmony). To understand what disturbs health, one must understand what determines health. The naturopathic physician evaluates a patient with reference to the determinants of health to discover wherein the patient's health is disturbed. In this step, the physician is essentially removing the obstacles to cure and allowing the vis medicatrix naturae to do its work.

Among these many possibilities, in general, the most significant are attitude diet, digestion, psychological and other stressers, and what might be called "spiritual integrity." Humans have a transpersonal dimension and can be seen as spiritual beings. Spirit here is not defined by religion or belief in a deity or deities; it is that component of the individual that gives rise to their inner compass, their "joie de vivre" and their internal meaning of life, their core beliefs, and their values. Perceived in this way, it can be seen that many people in society are experiencing "spiritual crises."[86] Although the general purview of the physician is the body, that instrument cannot be separated from the spirit that animates it. If the spirit is disturbed, the body cannot be fundamentally healthy. Hahnemann, the brilliant and insightful founder of homeopathy, instructed physicians to attend to the spirit.[122] Disturbance in the spirit permeates the body and eventuates in physical manifestation. Physicians are responsible

BOX 3-9 The Therapeutic Order: Hierarchy of Healing

1. **Establish the conditions for health**
 - Identify and remove disturbing factors
 - Institute a more healthful regimen
2. **Stimulate the healing power of nature *(vis medicatrix naturae):* the self-healing processes**
3. **Address weakened or damaged systems or organs**
 - Strengthen the immune system
 - Decrease toxicity
 - Normalize inflammatory function
 - Optimize metabolic function
 - Balance regulatory systems
 - Enhance regeneration
 - Harmonize with your life force[1]
4. **Correct structural integrity**
5. **Address pathology: Use specific natural substances, modalities, or interventions**
6. **Address pathology: Use specific pharmacologic or synthetic substances**
7. **Suppress or surgically remove pathology**

The actual therapeutic order may change, depending on the individual patient's needs for safe and effective care. The needs of the patient are primary in determining the appropriate approach to therapy.

Acute and chronic concerns are both addressed using the therapeutic order.[121] Acute concerns are addressed first to avoid further damage, risk, or harm to the patient. The point of entry for assessment and therapy is dependent on each patient's need for effective, safe care, healing, and prevention of suffering or degeneration.[1,121]

From Zeff J, Snider P. Course syllabus: NM5131, Naturopathic clinical theory. Seattle: Bastyr University, 1997-2005.

for perceiving such disturbances and addressing them. At colleges of naturopathic medicine in Australia, the United Kingdom, and North America, faculty work with naturopathic medicine students to develop their ability to perceive the spiritual nature of an individual as a foundational skill in addressing the spiritual crises or fundamental needs that have a profound effect on health and well-being. Using this definition, both atheists and agnostics can be seen to have a spiritual aspect. This definition also removes spirituality from religiosity in a way that does not denigrate any individual religious belief a patient may hold, allowing the naturopathic clinician to explore this aspect of the individual.

One of the oldest concepts in naturopathic medicine is the concept of toxemia. Toxemia is the generation and accumulation of metabolic wastes and exogenous toxins within the body. These toxins may be the results of maldigestive processes, intermediate metabolites, environmental xenobiotics, colon bacterial metabolites, etc. These toxins become irritants within the body, resulting in the inflammation of tissues and the ultimate interference with normal biochemical processes.[123] The maldigestive and dysbiotic[124,125] origin of these internally and externally derived toxins is the result of an inappropriate diet, broad spectrum antibiotics, and the effects of excessive stress on digestion.[126] Eating a diet that cannot be easily digested or that is out of appropriate nutrient balance for the individual results in the creation of metabolic toxins in the intestines.[124,125-127] Stress, causing the excessive secretion of cortisol and adrenalin, results in the decrease of blood flow to the digestive process, among other effects,[95-98,101] which decreases the efficient functioning of digestion and increases the tendency toward maldigestion, dysbiosis, and toxemia. Physicians can now easily measure the degree of toxemia in various ways (urinary indican or phenol[127]). The older concept of toxemia,[129,130] with scientific advances in its understanding[121,129] (Box 3-10), may now be productively combined with understanding of the newer concept of allostasis[95-98] and the historical[119,130] and re-emerging discussion on the inflammatory component of many, if not most, chronic diseases.* Spiritual disharmony, inappropriate diet, digestive disturbance, stress, and toxemia (leading to inflammation) are considered primary causes of chronic illness and must be addressed if healing is to occur. Beyond these, other disturbing factors must be discerned and addressed, whichever pertain to the individual patient.

Institute a Healthier Regimen

As a corollary of the first, once physicians have determined major contributing factors to illness, they construct a healthier regimen for the patient. Some disturbing factors can be eliminated, like inappropriate dietary elements.[82,83] Others are a matter of different choices or living differently.† The basics to consider are appropriate diet, appropriate rest and exercise, stress moderation, a healthy environment, and a good spiritual connection.

If this model is correct, these measures alone should result in enhanced health. The problem arises in knowing how to do these things. What is an appropriate diet? This is an area of considerable controversy. Physicians think about diet in many different ways. The goal of dietary improvement is to reduce the symptomatic consequences of the patient's diet and provide optimal nutrition to the patient. The point here, regardless of how this is done, is that it is central and essential for fundamental health improvement. If the diet is not correct, if digestion is not appropriate, if nutrition is not adequate, the patient cannot maximally improve, and the scene is potentially set for chronic inflammatory conditions and the re-setting of the adaptive allostatic and homeostatic set points. If the diet and digestion are appropriate, the basis for improvement in other areas is enhanced.

BOX 3-10 Scientific Considerations: Toxemia Today

Using conventional medical terminology, environmental, dietary, and lifestyle derived disorders are termed idiopathic environmental intolerances, multiple chemical sensitivities,[127,128,132,133] or sometimes oxidative stress disorders.[134-138] The terminology may be different, but it describes the same symptomatology. Environmental toxins accumulate, and chronic inflammation increases. These exogenous and endogenous toxins and the lack of exercise stress the system further. The ketogenic diet to control epilepsy may be considered one example of the successful application of diet to control symptoms.[103]

The same is true with these other fundamental elements, to which Lindlahr referred in the first element of his catechism, "return to nature": exercise, rest, dress, etc.[28] These have been expanded in the "determinants of health." They create the basis for improvement. What this really means is to change the "terrain," the conditions in which the disease has formed—not only to change but to improve the conditions so that there is less basis for the disease. Hahnemann addresses this on the first page of his *Organon of Medicine*.[122] He identified four tasks for the physician: to understand the true nature of illness, "what is to be cured"; to understand the healing potential of medicines; to understand obstacles to recovery and how to remove them; and to understand the elements that derange health and how to correct them so that recovery may be permanent.[122] Changing and improving the terrain in which the disease developed is the obvious first step in bringing about improvement. This sets up the basis for the following elements to have the most beneficial effects.

Stimulate the Self-Healing Mechanisms

A certain percentage of patients improve sufficiently simply by removing disturbing factors and establishing a healthier regimen. Most require more work. Once the patient is prepared, once the terrain is beginning to clear of disturbing factors, then one begins to apply stimulation to the self-healing mechanisms. The basis of this approach is the underlying recognition of the vis medicatrix naturae, the tendency of the body to be self-healing, the wisdom and intelligence within the system that constantly tends toward the healthiest expression of function, and the healing "forces" in the natural environment (air, water, light, etc.). The body heals itself. The physician can help create the circumstances to promote this. Then, as necessary, the physician stimulates the system. This also requires that attention be given to the patient's emotional state of mind, because the psychological condition of the patient is often of major importance.[140,141]

One of the best ways to do this is through constitutional hydrotherapy, as developed by Otis G. Carroll, ND, early in the past century. This procedure is simple, involving the placement of hot and then cold towels on the trunk and back, in specific sequence (depending on the patient), usually accompanied by a sine wave stimulation of the digestive tract. This is a dynamic treatment, simple, inexpensive, and universally applicable. It helps recover digestive function, stimulates toxin elimination, "cleans the blood," enhances immune function, and has several other effects. It moves the system along toward a healthier state.[142] Exercise

often achieves similar results. Many naturopathic modalities can be used to stimulate the overall vital force.

More specific approaches to stimulation, although general in effect, are applied differently to each patient and have a less general effect than those previously mentioned. Homeopathy and acupuncture[143-145] are often the primary methods of such stimulation. They add little to the system; they are not gross chemical treatments. They work with what is there, stimulating a reaction, stimulating function, and correcting disturbed patterns.

Each method helps move the system out of its disturbed state and, with the reduction of encumbrance, helps move it toward health.

Finally, exposure to the patterns, rhythms, and forces of nature is a traditional part of naturopathic medicine and the tradition of nature doctors throughout the world. As previously noted, "We exist as part of complex patterns of matter, energy, and spirit,"[1] and the natural progression of these patterns and the drive toward health inherent in them, is a natural ally for the physician. Exposure to appropriate rhythms, patterns, and forces of nature strengthens vitality and stimulates the healing power of nature.

Support Weakened or Damaged Systems or Organs

Some systems or functions require more than stimulation to improve. Some organs are weakened or damaged (e.g., adrenal fatigue after prolonged stress), and some systems are blocked or congested (e.g., the hepatic detoxification pathways) and require extra help. This is where naturopathic physicians use their vast natural medicinary. Botanical medicines can affect any system or organ, enhancing its function, improving its circulation, providing specific nutrition, and stimulating repair. Glandular substances can be applied to a similar purpose. Plus, there are the growing number of evidence-based "nutraceuticals"—biological compounds that enhance metabolic pathways and provide substance for metabolic function.[146-157]

Naturopathic physicians can also apply specific homeopathic medications, usually in the lower potencies, which act nutritively and can stimulate specific organs or functions. This method, generally referred to as drainage, can be used to stimulate detoxification of specific substances from the body in general or of specific organ systems or tissues. Dr. Pizzorno's work in *Total Wellness*,[158] the work of "functional medicine" leader Jeffrey Bland, PhD, and the *Textbook of Functional Medicine* by Jones[120] exemplify the clinical strategies applied at this level of the therapeutic order. These strategies are used to restore optimal function to an entire physiologic system (immune, cardiovascular, detoxification, life force, endocrine).[158]

One can also use specific exercises to stimulate or enhance organ health. Some systems of Yoga and Qi Gong are organ specific. Specific applications of hydrotherapy and other physiotherapy systems can be applied to enhance the function of organs or tissues.

It has been the clinical experience of many naturopathic physicians that these methods, combined with an appropriate diet and a healthier regimen, along with constitutional hydrotherapy, appropriate homeopathy, and acupuncture, bring most health problems back to normal, without negative consequence, rapidly, efficiently, and permanently.

Address Structural Integrity

Many structural problems result from generalized stress of some kind on internal systems. For example, mid-back misalignment or discomfort (T1–T12) is often found associated with a history of underlying stress on the digestive organs, the enervation of which originates at those spinal segments. One can manipulate the vertebra back into proper alignment or massage contracted musculature, but until one corrects the underlying functional disturbance, there will be a tendency to repeated structural misalignment. In some circumstances, the singular problem may be simply structural disintegrity. One may have fallen or been hit in some fashion and simply needs the neck manipulated back into proper alignment and the surrounding soft tissue relaxed. There may be no dietary error or other disturbance aside from the original injury, and correction requires only simple manipulation or therapeutic massage. This is an example of the flexibility of the therapeutic order concept. In this case, first-order therapeutics manipulate the cervical spine or relax chronically contracted muscles. Usually, however, the problem of structure is part of the larger problem, and such intervention becomes a fourth-order therapeutic.[64]

Reintegrating structure can occur in many ways, one of which is the method of "bone cracking" known to the ancient Greeks and Chinese and probably all other ancient healing cultures. However, there are nonforce manipulative systems that include many modalities of therapeutic massage. Some systems of exercise are designed to reintegrate and maintain normal structural relationships. Any of these might be appropriate to a specific patient. By approaching the problem in the context of the therapeutic order, one can expect structural corrections to be required only occasionally and for the results to be more or less permanent.

Address Pathology: Use Specific Natural Substances, Modalities, or Interventions

Having gone through the first four steps of this therapeutic hierarchy, most patients improve. The improvement is based on the sound footing of the underlying correction or removal of fundamental causative elements. It is also based on the intrinsic nature of the body to heal itself using the least possible force. Most pathology improves or disappears under these circumstances. Sometimes it is necessary to address pathology. This may be the case because the particular pathology may be threatening to life or limb. Acting on this threat is imperative. It can be done often with naturopathic means, directed specifically against the pathology. Biochemical or genetic individuality also can demand an emphasis at this level of intervention.

One of the major conflicts in naturopathic medicine is that some practitioners find it expedient to diagnose and treat pathology (the standard medical model) rather than pursue a naturopathic model of practice. This approach tends to be less satisfying and less productive of the most elegant outcomes and the long-term continued health of the patient. It also reduces the capacity of the physician to treat, such as in cases where there is no evidence-based treatment for the pathology in question, or where there is no clear diagnosis (i.e., no distinct pathology to treat). This approach is increasingly referred to as "green allopathy." However, the vast body of knowledge that naturopathic education presents in this arena makes such an approach seductive, especially in a culture that more or less expects, supports, reinforces, and pays for an "allopathic" approach to diagnosis and treatment.

It is easy to do this. The culture is accustomed to this model and often expects to encounter this in the naturopathic physician's office. In some states, such as Oregon, Washington, and Arizona, where the naturopathic formulary includes most antibiotics and many pharmaceutical drugs, one can practice almost without distinction from a medical doctor. The typical naturopathic formulary is often sufficient to prescribe on a strictly pathologic basis.

The problem with this is that it is generally not as effective, especially in the treatment of chronic disease. The value of naturopathic medicine in our culture is not that naturopathic physicians can function almost like medical doctors, with a "natural" formulary instead of drugs. It is that they offer a fundamentally different approach, one based on the restoration of health rather than the treatment of disease.

Given all of this, it still may be useful to directly address the pathologic entity or its etiology.[159-163] When treating an antibiotic-resistant infection, for example, it may be useful to apply botanical medicines with specific antibiotic properties, along with immune tonics and the more fundamental steps of this therapeutic hierarchy. In difficult cases, such as many cancers, using agents that have specific, pathology-based therapeutics may be an essential element of comprehensive treatment. The naturopathic formulary provides a vast and increasing number of such options. One advantage of such treatment is that, in general, when applied by a knowledgeable practitioner, it rarely adds more burden or toxicity to the system. Naturopathic pathology-based treatments still follow the dictum "do no harm."

Address Pathology: Use Specific Pharmacologic or Synthetic Substances

About 800,000 medical doctors and osteopathic physicians in the United States are trained in the science of pathologic-based treatment, using pharmaceuticals and surgery, etc. There are times when such an approach is necessary to preserve life, limb, or function. Although some naturopathic physicians, by training and by statute, may prescribe pharmaceuticals or perform minor office procedures and surgeries, naturopathic physicians may also refer patients in need of such services to appropriate medical doctors or osteopaths. In a growing number of states, NDs can legally provide an expanding range of prescription drugs. Although this is an important tool for the naturopathic primary caregiver, this privilege requires enhanced responsibility for the ND to prescribe those substances only as needed—and to thoroughly rely on applying the least force appropriate to effect recovery and protect patient safety. Both Dr. Lust (at the end of his life) and Dr. Bastyr recognized the need for NDs to have the ability to access, as needed, prescriptive medications and perform minor office procedures to function as primary caregivers. However, both admonished that the philosophy and principles of the medicine guide their judicious use—only as truly needed, based on the least force necessary to restore the patient to health.

Naturopathic physicians are well trained in this regard and respect the necessity and utility of standard medical practice in appropriate situations. Some disagreement exists regarding which situations may be appropriate. The AANP developed position papers to resolve some of these questions.

In general, although recognizing the necessity of such treatment, most naturopathic physicians also recognize that such treatment often carries consequences that also must be addressed.

Suppress Pathology

Sometimes it is necessary when there is risk of harm to the patient's health or tissue, or to relieve suffering, to suppress pathology. Medical doctors are especially trained in this art and have powerful and effective tools with which to do this. Unfortunately, suppression, because it does not fundamentally remove or address essential causative factors (such as dietary error) often results in the development of other, often deeper disturbance or pathology. Because much pathologic expression is the result of the actual self-healing mechanisms (e.g., inflammation), suppressive measures are, in general, anti–vis medicatrix naturae. The result of suppression is that the fundamental disturbing factors are still at play within the person, still disrupting function to some extent, whereas the suppression reduces the symptomatic expression and resolution of disturbance. One simple example of this is the over use of corticosteroidal anti-inflammatory and antihistaminic drugs in the treatment of acute asthma. This usually effectively opens the airways. However, prolonged use weakens the patient. If the treatment persists, the patient becomes immune compromised and osteoporotic and can develop psychological disorders. These symptoms are part of the long-term effects of steroids.[74] It may necessarily maintain breathing, but the long-term cost to the organism is high.

Suppression, although it may be life saving, often has serious consequences. With standard medical methods of care, cure of chronic illness is often elusive. This is the benefit of the naturopathic approach: by taking a nonsuppressive course of action, based on sound physiologic principles, one can often restore health without recourse to the potential damage of suppression. Naturopathic physicians, although recognizing the occasional necessity of suppressive approaches, in general avoid suppression, which is a primary way in which physicians can inflict harm, even with the best of intentions.

THEORY IN NATUROPATHIC MEDICINE

This therapeutic hierarchy is based on the observation of the nature of healing and the inherent order of the healing process. It is part of a unifying theory of naturopathic medicine, an outgrowth of the principles that underlie naturopathic thinking. It provides the physician with instructions that order the many therapeutic modalities used by the practice.

The consensus definition of naturopathic medicine, adopted by the AANP in 1989, is a statement of identity, distinguishing naturopathic medicine from other systems of medical thought. Contained within it is a set of instructions regarding the practice of the medicine. The three concepts discussed here—"disease as process," "the determinants of health," and "the therapeutic order"—are an articulation of these instructions. They are presented as a clinical theory of naturopathic medicine. They have been crystallized, as is the definition, from the observation by nature doctors throughout time and across many traditions of the nature of health, disease, and healing. They provide the physician with instructions. These instructions include a procedure for thinking about human illness in such a way that one can approach its cure in an ordered fashion by understanding its process as an expression of the vis medicatrix naturae. It provides the framework for truly evaluating the patient as a whole being: spiritual, mental/emotional, and physical, rather than as a category of pathology. Plus, it provides the physician a system for organizing and efficiently integrating the vast therapeutic array provided in naturopathic medicine. Ultimately, it satisfies Hahnemann's observation of the ideal role of medicine, that "the highest ideal of cure is rapid, gentle and permanent restoration of the health … in the shortest, most reliable and most harmless way, upon easily comprehensible principles."[122] The roots of the observations that form this theory are traceable through the mid- and early-twentieth century, to the traditional theory of nineteenth-century European nature cure, and to the roots and theories of traditional world

medicines. Hippocrates' writings on the vis medicatrix naturae form a foundation that historically underpins the development of this theory.[164,165]

Finally, it is observable across many traditional world medicines that various healing orders are described. Such structures hold implications for public and community health priorities and suggest the reprioritization of health care priorities and financing. Implications for public policy and the growing national disease debt invite exploration.

Although this presentation is not comprehensive, the attempt has been made to demonstrate these roots, at least in some of their major articulations. The work presented here is a continuation of this historical process, which ultimately is driven by the true mission of the physician: to ease suffering and to preserve life.

INTRODUCTION

Naturopathy, as a generally used term, emerged in America from the writings and promotion of Benedict Lust. Naturopathy, or "nature cure," is both a way of life and a concept of healing that employs various natural means of treating human infirmities and disease states. The earliest mechanisms of healing associated with the term, as used by Lust, involved a combination of hygienics and hydropathy (hydrotherapy). The term itself was coined in 1895 by Dr. John Scheel of New York City to describe his method of health care. However, earlier forerunners of these concepts already existed in the history of natural healing, both in America and in the Austro-Germanic European core.

Lust came to this country from Germany in the 1890s as a disciple of Father Sebastian Kneipp, a Dominican priest, and as an emissary dispatched by Father Kneipp to bring hydrotherapy to America. Lust purchased the term "naturopathy" from Scheel in 1902 to describe the eclectic compilation of doctrines of natural healing that he envisioned to be the future of natural medicine. In January 1902, Lust, who had been publishing the *Kneipp Water Cure Monthly* and its German language counterpart in New York since 1896, changed the name of the journal to *The Naturopath and Herald of Health* and evoked the dawn of a new health care era with the following editorial:

> *Naturopathy is a hybrid word. It is purposely so. No single tongue could distinguish a system whose origin, scope and purpose is universal—broad as the world, deep as love, high as heaven. Naturopathy was not born of a sudden or a happen-so. Its progenitors have for eons been projecting thoughts and ideas and ideals whose culminations are crystallized in the new Therapy. Connaro, doling out his few fixed ounces of food and drink each day in his determined exemplification of Dietotherapy; Priessnitz, agonizing, despised and dejected through the long years of Hydropathy's travail; the Woerishofen priest, laboring lovingly in his little parish home for the thousands who journeyed Germany over for the Kneipp cure; Kuhne, living vicariously and dying a martyr for the sake of Serotherapy; A.T. Still, studying and struggling and enduring for his faith in Osteopathy; Bernarr Macfadden, fired by the will to make Physical Culture popular; Helen Willmans, threading the mazes of Mental Science, and finally emerging triumphant; Orrison Sweet Maraden, throbbing in sympathy with human faults and failures, and longing to realize Success to all mankind—these and hosts of others have brought into being single systems whose focal features are perpetuated in Naturopathy.*
>
> *Jesus Christ—I say it reverently—knew the possibility of physical immortality. He believed in bodily beauty; He founded Mental Healing; He perfected Spirit-power. And Naturopathy will include ultimately the supreme forces that made the Man of Galilee omnipotent.*
>
> *The scope of Naturopathy is from the first kiss of the new-found lovers to the burying of the centenarian whose birth was the symbol of their perfected one-ness. It includes ideally every life-phase of the id, the embryo, the foetus, the birth, the babe, the child, the youth, the man, the lover, the husband, the father, the patriarch, the soul.*
>
> *We believe in strong, pure, beautiful bodies thrilling perpetually with the glorious power of radiating health. We want every man, woman and child in this great land to know and embody and feel the truths of right living that mean conscious mastery.*

We plead for the renouncing of poisons from the coffee, white flour, glucose, lard, and like venom of the American table to patent medicines, tobacco, liquor and the other inevitable recourse of perverted appetite. We long for the time when an eight-hour day may enable every worker to stop existing long enough to live; when the spirit of universal brotherhood shall animate business and society and the church; when every American may have a little cottage of his own, and a bit of ground where he may combine Aerotherapy, Heliotherapy, Geotherapy, Aristophagy and nature's other forces with home and peace and happiness and things forbidden to flat-dwellers; when people may stop doing and thinking and being for others and be for themselves; when true love and divine marriage and pre-natal culture and controlled parenthood may fill this world with germ-gods instead of humanized animals.

In a word, Naturopathy stands for the reconciling, harmonizing and unifying of nature, humanity and God.

Fundamentally therapeutic because men need healing; elementally educational because men need teaching; ultimately inspirational because men need empowering, it encompasses the realm of human progress and destiny.

Perhaps a word of appreciation is due Mr. John H. Scheel, who first used the term "Naturopathic" in connection with his Sanitarium "Badekur," and who has courteously allowed us to share the name. It was chosen out of some 150 submitted, as most comprehensive and enduring. All our present plans are looking forward some five or ten or fifty years when Naturopathy shall be the greatest system in the world.

Actually the present development of Naturopathy is pitifully inadequate, and we shall from time to time present plans and ask suggestions for the surpassing achievement of our world-wide purpose. Dietetics, Physical Culture and Hydropathy are the measures upon which Naturopathy is to build; mental culture is the means, and soul-selfhood is the motive.

If the infinite immensity of plan, plea and purpose of this particular magazine and movement were told you, you would simply smile in your condescendingly superior way and straightway forget. Not having learned as yet what a brain and imagination and a will can do, you consider Naturopathy an ordinarily innocuous affair, with a lukewarm purpose back of it, and an ebbing future ahead of it. Such is the character of the average wishy-washy health movement and tumultuous wave of reform.

Your incredulous smile would not discomfit us—we do not importune your belief, or your help, or your money. Wherein we differ from the orthodox self-labeled reformer, who cries for sympathy and cringes for shekels.

We need money most persistently—a million dollars could be used to advantage in a single branch of the work already definitely planned and awaiting materialization; and we need co-operation in a hundred different ways. But these are not the things we expect or deem best.

Criticism, fair, full and unsparing is the one thing of value you can give this paper. Let me explain. Change is the keynote of this January issue—in form, title, make-up. If it please you, your subscription and a word to your still-benighted friends is ample appreciation. But if you don't like it, say so. Tell us wherein the paper is inefficient or redundant or ill-advised, how it will more nearly fit into your personal needs, what we can do to make it the broadest, deepest, truest, most inspiring of the mighty host of printed powers. The most salient letter of less than 300 words will be printed in full, and we shall ask to present the writer with a subscription-receipt for life.

By to-morrow you will probably have forgotten this request; by the day after you will have dropped back into your old ways of criminal eating and foolish drinking and sagged standing and congested sitting and narrow thinking and deadly fearing—until the next progress paper of New Thought or Mental Science or Dietetics or Physical Culture prods you into momentary activity.

Between now and December we shall tell you just how to preserve the right attitude, physical and mental, without a single external aid; and how, every moment of every day, to tingle and pulsate and leap with the boundless ecstasy of manhood consciously nearing perfection.

A BRIEF HISTORY OF EARLY AMERICAN MEDICINE WITH AN EMPHASIS ON NATURAL HEALING

To understand the evolutionary history of naturopathic medicine in this country, it is necessary to view the internal development of the profession against the historical, social, and cultural backdrop of American social history.

Medicine in America: 1800–1875

In the America of 1800, although a professional medical class existed, medicine was primarily domestically oriented. An individual who fell ill was commonly nursed by a friend or family member who relied upon William Buchan's *Domestic Medicine* (1769), John Wesley's *Primitive Physic* (1747), or John Gunn's *Domestic Medicine* (1830).[1]

Professional Medicine

Professional medicine transferred from England and Scotland to America in pre-revolutionary days. However, eighteenth and early nineteenth century America considered the concept of creating a small, elite, learned profession to run counter to the political and institutional concepts of early American democracy.[1]

The first medical school in the American colonies opened in 1765 at what was then the College of Philadelphia (later the University of Pennsylvania), and the school was dominated by revolutionary leader and physician Benjamin Rush, a signatory to the Declaration of Independence. The proliferation of medical schools to train the new professional medical class began seriously after the war of 1812. Between 1810 and 1820, new schools were established in Baltimore, Lexington, Cincinnati, and even in rural communities in Vermont and Western New York. Between 1820 and 1850 a substantial number of schools were established in the western rural states. By 1850, there were 42 medical schools recognized in the United States, although there were only three in all of France.

Generally, these schools were started by a group of five to seven local physicians approaching a local college with the idea of establishing a medical school in conjunction with the college's educational facilities. The schools were largely apprenticeship based, and the professors received their remuneration directly from fees paid by the students.

The requirements for a Doctor of Medicine (MD) degree in late eighteenth and early nineteenth century America were roughly as follows:

- Knowledge of Latin and natural and experimental philosophy
- Three years of serving an apprenticeship under practicing physicians

- Attending two terms of lectures and passing of attendant examinations
- A thesis

Graduating students had to be at least 21 years of age.[1]

The rise of any professional class is gradual and marked by difficulties, and varying concepts existed as to the demarcation of a "professional" physician. Contrasts included graduates of medical school versus nongraduates, medical society members versus nonmembers, and licensed physicians versus unlicensed "doctors." Licensing statutes came into existence between 1830 and 1850, but were soon repealed, as they were considered "undemocratic" during the apex of Jacksonian democracy.[1]

Thomsonianism

In 1822 the rise in popularity of Samuel Thomson and his publication of *New Guide to Health* helped to frustrate the creation of a professional medical class. Thomson's work was a compilation of his personal view of medical theory and American Indian herbal and medical botanical lore. Thomson espoused the belief that disease had one general cause—"cold" influences on the human body—and that disease had therefore one general remedy—"heat." Unlike the followers of Benjamin Rush and the American "heroic" medical tradition who advocated blood-letting, leeching, and the substantial use of mineral-based purgatives such as antimony and mercury, Thomson believed that minerals were sources of "cold" because they came from the ground and that vegetation, which grew toward the sun, represented "heat."[1]

As noted in Griggs' *Green Pharmacy* (the best history of herbal medicine to date), Thomson's theory developed as follows[2]:

> *Instead, he elaborated a theory of his own, of the utmost simplicity: "All diseases … are brought about by a decrease or derangement of the vital fluids by taking cold or the loss of animal warmth … the name of the complaint depends upon what part of the body has become so weak as to be affected. If the lungs, it is consumption, or the pleura, pleurisy; if the limbs, it is rheumatism, or the bowels, colic or cholera morbus … all these different diseases may be removed by a restoration of the vital energy, and removing the obstructions which the disease has generated …"*
>
> *Thus the great object of his treatment was always to raise and restore the body's vital heat: "All … that medicine can do in the expulsion of disorder, is to kindle up the decaying spark, and restore its energy till it glows in all its wonted vigor."*

Thomson's view was that individuals could be self-treating if they had a sincere "guide to health" philosophy and a copy of his book, *New Guide to Health*. The right to sell "family franchises" for use of the Thomsonian method of healing was the basis of a profound lay movement between 1822 and Thomson's death in 1843. Thomson adamantly believed that no professional medical class should exist and that democratic medicine was best practiced by laypersons within a Thomsonian "family" unit.

By 1839, Thomson claimed to have sold some 100,000 of these family franchises called "friendly botanic societies." Although he professed to have solely the interests of the individual at heart, his system was sold at a profit under the protection of a patent he obtained in 1813.

The Eclectic School of Medicine

Some of the "botanics" (professional Thomsonian doctors) wanted to separate themselves from the lay movement by creating requirements and standards for the practice of Thomsonian medicine. Thomson, however, was adamantly against a medical school founded on his views. Thus, it was not until the decade after Thomson's death that independent Thomsonians founded a medical college (in Cincinnati) and began to dominate the Thomsonian movement. These Thomsonian botanics were later absorbed into the medical sectarian movement known as the "eclectic school," which originated with the New Yorker Wooster Beach.

Beach was another of medical history's fascinating characters. From a well-established New England family, he started his medical studies at an early age, apprenticing under an old German herbal doctor, Jacob Tidd. After Tidd died, Beach enrolled in the Barclay Street Medical University in New York. Griggs[2] described the following:

> *Beach's burning ambition was to reform medical practice generally—not to alienate the entire profession by savage attacks from without—and he was convinced that he would be in a stronger position to do so if he were himself a diplomatized doctor. The faculty occasionally listened to criticism from within their own number: against onslaughts of "illiterate quacks" like Samuel Thomson, they simply closed ranks in complacent hostility.*

After opening his own practice in New York, Beach set out to win over fellow members of the New York Medical Society (into which he had been warmly introduced by the screening committee) to his point of view that heroic medicine was inherently dangerous to mankind and should be reduced to the gentler theories of herbal medicine. He was summarily ostracized from the medical society.

To Beach this was a bitter blow, but he soon founded his own school in New York, calling the clinic and educational facility "The United States Infirmary." However, due to continued pressure from the medical society, he was unable to obtain charter authority to issue legitimate diplomas. He then located a financially ailing but legally chartered school, Worthington College, in Ohio. He opened a full-scale medical college; out of its classrooms he launched what became known as the *Eclectic School of Medical Theory.* Griggs related the following[2]:

> *Beach had a new name for his practice: While explaining to a friend his notions of combining what was useful in the old practice with what was best in the new, the friend exclaimed, "You are an eclectic!" to which, according to legend, Beach replied, "You have given me the term which I have wanted: I am an eclectic!"*

Cincinnati subsequently became the focal point of the eclectic movement, and the E. M. Institute medical school remained until 1938 (the last eclectic school to exist in America).[3] The concepts of this sect helped to form some of the theoretical underpinnings of Lust's naturopathy. Lust himself graduated from the Eclectic Medical College of the City of New York in the first decade of the 1900s.

Despite his criticism of the early allopathic movement (although the followers of Rush were not as yet known by the term "allopath," reputed to have been coined by Samuel Hahnemann) for their "heroic" tendencies, Thomson's medical theories were "heroic" in their own fashion. Although he did not advocate blood-letting, heavy metal poisoning, and leeching, botanic purgatives—particularly *Lobelia inflata* (Indian tobacco)—were a substantial part of the therapy.

The Hygienic School of Thought

One other forerunner of American naturopathy, also originating as a lay movement, grew into existence at this time. This was the "hygienic" school, which had its genesis in the popular teachings of Sylvester Graham and William Alcott.

Graham began preaching the doctrines of temperance and hygiene in 1830. In 1839, he published *Lectures on the Science of Human Life*, two hefty volumes that prescribed healthy dietary habits. He emphasized a moderate lifestyle, recommending an anti-flesh diet and bran bread as an alternative to bolted or white bread.

Alcott dominated the scene in Boston during this same period and, together with Graham, saw that the American hygienic movement—at least as a lay doctrine—was well established.[4]

Homeopathy

By 1840, the profession of homeopathy had also been transplanted to America from Germany. Homeopathy, the creation of an early German physician, Samuel Hahnemann (1755–1843), had three central doctrines:

- The "law of similars" (that like cures like)
- That the effect of a medication could be heightened by its administration in minute doses (the more diluted the dose, the greater the "dynamic" effect)
- That nearly all diseases were the result of a suppressed itch, or "psora"

The view was that a patient's natural symptom-producing disease would be displaced after homeopathic medication by a similar, but much weaker, artificial disease that the body's immune system could easily overcome.

Originally, most homeopaths in this country were converted orthodox medical men, or "allopaths." The high rate of conversion made this particular medical sect the archenemy of the rising orthodox medical profession. (For a more detailed discussion of homeopathy, see Chapter 39.)

The first homeopathic medical school was founded in 1850 in Cleveland; the last purely homeopathic medical school, based in Philadelphia, survived into the early 1930s.[1]

The Rise and Fall of the Sects

Although these two nonallopathic sects were popular, they never comprised more than one fifth of the professional medical class in America. Homeopathy at its highest point reached roughly 15%, and the eclectic school roughly 5%. However, their very existence for many years kept the exclusive recognition desired by the orthodox profession from coming within its grasp. Homeopathy was distasteful to the more conventional medical men not only because it resulted in the conversion of a substantial number of their peers, but also because homeopaths generally also made a better income. The rejection of the eclectic school was more fundamental: it had its roots in a lay movement that challenged the validity of a privileged professional medical class.

The existence of three professional medical groups—the orthodox school, the homeopaths, and the eclectics—combined with the Jacksonian view of democracy that prevailed in mid-nineteenth century America, resulted in the repeal of virtually all medical licensing statutes existing before 1850. However, by the 1870s and 1880s, all three medical groups began to voice support for the restoration of medical licensing.

Views differ as to what caused the homeopathic and eclectic schools to disappear from the medical scene in the 50 years after 1875. One view defined a sect as follows[5]:

> *A sect consists of a number of physicians, together with their professional institutions, who utilize a distinctive set of medically invalid therapies which are rejected by other sects …*

By this definition, the orthodox or allopathic school was just as sectarian as the homeopathic and eclectic schools. Rothstein's view was that these two nineteenth century sects disappeared because, beginning in the 1870s, the orthodox school grasped the European idea of "scientific medicine." Based on the research of such men as Pasteur and Koch and the "germ theory," this approach supposedly proved to be the medically proper view of valid therapy and gained public recognition because of its truth.

Another view was that the convergence of the needs of the three sects for professional medical recognition (which began in the 1870s and continued into the early 1900s) and the "progressive era" led to a political alliance in which the majority orthodox school was ultimately dominant by sheer weight of numbers and internal political authority. Starr[1] noted the following:

> *Both the homeopaths and eclectics wanted to share in the legal privileges of the profession. Only afterward did they lose their popularity. When homeopathic and eclectic doctors were shunned and denounced by the regular profession, they thrived, but the more they gained an access to the privileges of regular physicians, the more their numbers declined. The turn of the century was both the point of acceptance and the moment of incipient disintegration …*

In any event, this development was an integral part of the drive toward professional authority and autonomy established during the progressive era (1900–1917). It was acceptable to the homeopaths and the eclectics because they controlled medical schools that continued to teach and maintain their own professional authority and autonomy. However, it was after these professional goals were attained that the lesser schools of medical thought went into rapid decline.[1]

The American Influence

From 1850 to 1900, the medical counterculture continued to establish itself in America. From its lay roots in the teachings of the hygienic movement grew professional medical recognition, albeit a small minority and "irregular" view, that hygiene and hydropathy were the basis of sound medical thought (much like the Thomsonian transition to botanic and eclectic medicine).

Trall

The earliest physician who had a significant impact on the later growth of naturopathy as a philosophical movement was Russell Trall, MD. As noted in James Whorton's *Crusaders for Fitness*,[4] he "passed like a meteor through the American hydropathic and hygienic movement":

> *The exemplar of the physical educator-hydropath was Russell Thatcher Trall. Still another physician who had lost his faith in regular therapy, Trall opened the second water cure establishment in America, in New York City in 1844. Immediately he combined the full Preissnitzian armamentarium of baths with regulation of diet, air, exercise and sleep. He would eventually open and or direct any number of other hydropathic institutions around the country, as well as edit the Water-Cure Journal, the Hydropathic Review, and a temperance journal. He authored several books, including popular sex manuals which perpetuated Graham-like concepts into the 1890's, sold Graham crackers and physiology texts at his New York office, was a charter member (and officer) of the American Vegetarian Society, presided over a short-lived World Health Association, and so on. His crowning accomplishment was the Hygeian Home, a "model Health Institution [which] is beautifully situated on the Delaware River between Trenton and Philadelphia." A drawing presents it as a palatial establishment with expansive grounds for walking and riding, facilities for rowing,*

sailing, and swimming, and even a grove for open-air "dancing gymnastics." It was the grandest of water cures, and lived beyond the Civil War period, which saw the demise of most hydropathic hospitals. True, Trall had to struggle to keep his head above water during the 1860's, but by the 1870's he had a firm financial footing (being stabilized by tuition fees from the attached Hygeio-therapeutic College). With Trall's death in 1877, however, the hydropathic phase of health reform passed.

As evident later in this chapter, this plethora of activity was similar to that engaged in by Benedict Lust between 1896 and his death in 1945, when he worked to establish naturopathy. The Hygeian Home and later "Yungborn" establishments at Butler, New Jersey, and Tangerine, Florida, were similar to European nature cure sanitariums, such as the original Yungborn founded by Adolph Just and the spa/sanitarium facilities of Preissnitz, Kneipp, and Just.

Trall gave a famous address to the Smithsonian Institution in Washington, DC, in 1862, under the sponsorship of the Washington Lecture Association. "The true healing art: or hygienic vs drug medication," a 2.5-hour lecture purported to have received rapt attention, was devoted to Trall's belief in the hygienic system and in hydropathy as the true healing art. The address was reprinted by Fowler and Wells (New York, 1880) with an introduction written by Trall, before his death in 1877.

Trall also founded the first school of natural healing arts in this country to have a 4-year curriculum and the authorization to confer the degree of MD. It was founded in 1852 as a "hydropathic and physiological school" and was chartered by the New York State Legislature in 1857 under the name "New York Hygio-Therapeutic College," with the legislature's authorization to confer the MD degree.

In 1862, Trall went to Europe to attend the International Temperance Convention. He took a prominent part at this meeting of reformers, specifically related to the use of alcohol as a beverage and as a medicine. He eventually published more than 25 books on the subjects of physiology, hydropathy, hygiene, vegetarianism, and temperance, among many others.

The most valuable and enduring of these was his *Hydropathic Encyclopedia*, a volume of nearly 1000 pages that covered the theory and practice of hydropathy and the philosophy and treatment of diseases advanced by older schools of medicine. At the time of his death, according to the December 1877 *Phrenological Journal* cover article featuring a lengthy obituary of Trall, this encyclopedia had sold more than 40,000 copies since its original publication in 1851.

For more than 15 years, Trall was editor of the *Water-Cure Journal* (also published by Fowler and Wells). During this period, the journal went through several name changes, including the *Hygienic Teacher* and *The Herald of Health*. When Lust originally opened the American School of Naturopathy, an English-language version of *Kneipp's Water-cure* (or in German *Meine Wasser-kurr*) being unavailable, he used only the works and writings of Trall as his texts.

By 1871, Trall moved from New York to the Hygeian Home on the Delaware River. His water-cure establishment in New York became The New Hygienic Institute. One of its co-proprietors was Martin Luther Holbrook, who later replaced Trall as the editor of *The Herald of Health*. Professor Whorton noted the following[4]:

But Holbrook's greatest service to the cause was as an editor. In 1866 he replaced Trall at the head of The Herald of Health, which had descended from the Water-Cure Journal and Herald of Reforms (1845-1861) by the way of the Hygienic Teacher and Water-Cure Journal (1862). Under Holbrook's direction the periodical would pass through two more name changes (Journal of Hygiene Herald of Health, 1893-1897, and Omega, 1898-1900) before merging with Physical Culture.

Trall and Holbrook both advanced the idea that physicians should teach the maintenance of health rather than simply provide a last resort in times of health crisis. Besides providing a strong editorial voice espousing vegetarianism, the evils of tobacco and drugs, and the value of bathing and exercise, dietetics and nutrition, along with personal hygiene, were strongly advanced by Holbrook and others of the hygienic movement during this era. Whorton described the idea as follows[4]:

The orthodox hygienists of the progressive years were equally enthused by the recent progress of nutrition, of course, and exploited it for their own ends, but their utilization of science hardly stopped with dietetics. Medical bacteriology was another area of remarkable discovery, bacteriologists having provided, in the short space of the last quarter of the 19th century, an understanding, at long last, of the nature of infection. This new science's implications for hygienic ideology were profound—when Holbrook locked horns with female fashion, for example, he did not attack the bulky, ground-length skirts still in style with the crude Grahamite objection that the skirt was too heavy. Rather he forced a gasp from his readers with an account of watching a smartly dressed lady unwittingly drag her skirt "over some virulent, revolting looking sputum, which some unfortunate consumptive had expectorated."

Holbrook expanded on the work of Graham, Alcott, and Trall and, working with an awareness of the European concepts developed by Preissnitz and Kneipp, laid further groundwork for the concepts later advanced by Lust, Lindlahr, and others[4]:

For disease to result, the latter had to provide a suitable culture medium, had to be susceptible. As yet, most physicians were still so excited at having discovered the causative agents of infection that they were paying less than adequate notice to the host. Radical hygienists, however, were bent just as far in the other direction. They were inclined to see bacteria as merely impotent organisms that throve only in individuals whose hygienic carelessness had made their body compost heaps. Tuberculosis is contagious, Holbrook acknowledged, but "the degree of vital resistance is the real element of protection. When there is no preparation of the soil by heredity, predisposition or lowered health standard, the individual is amply guarded against the attack." A theory favored by many others was that germs were the effect of disease rather than its cause; tissues corrupted by poor hygiene offered microbes, all harmless, an environment in which they could thrive.

In addition to introducing the works of Kneipp and his teachings to the American hygienic health care movement, Holbrook was a leader of the fight against vivisection and vaccination[4]:

Vivisection and vaccination were but two of the practices of medicine criticized in the late 19th century. Therapy also continued to be an object of protest. Although the heroism of standard treatment had declined markedly since mid-century, a prescription was still the reward of any visit to the doctor, and drugless alternatives to healing were appearing in protest. Holbrook published frequent favorable commentaries on the revised water cure system of Germany's Kneipp. A combination of baths, herbal teas, and hardening exercises, the system had some vogue in the 1890's before flowering into naturopathy. Holbrook's journal also gave

positive notices to osteopathy and "chiropathy" [chiropractic], commending them for not going to the "drugstore or ransack[ing] creation for remedies nor load[ing] the blood with poison." But though bathing and musculoskeletal manipulation were natural and nonpoisonous, Holbrook preferred to give the body complete responsibility for healing itself. Rest and proper diet were the medicines of this doctor who billed himself as a "hygienic physician" and censured ordinary physicians for being engrossed with disease rather than health.

The Beginnings of "Scientific Medicine"

While the hygienic movement was making its impact, the orthodox medical profession, in alliance with the homeopaths and eclectics, was making significant advances. The orthodox profession, through the political efforts of the American Medical Association (AMA), first tried to remove sectarian and irregular practitioners by segregating them from the medical profession altogether. It did so by formulating and publishing its first national medical code of ethics in 1847. (In 1846 the orthodox profession formed the AMA to represent their professional views.) The code condemned proprietary patents (even carrying over into a physician's development of surgical or other medical implements, which led to its greatest criticism); encouraged the adoption of uniform rules for payment in geographic areas; condemned the practice of contract work; prohibited advertising and fee-sharing even among specialists and general practitioners; eliminated blacks and women; and, most significantly, prohibited any consultation or contact with irregulars or sectarian practitioners. The code stated the following[6]:

No one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry.

In the late 1870s and into the 1880s, the major sects—the orthodox or allopathic school, the homeopaths, and the eclectics—began to find more reason to cooperate to obtain common professional goals. These included the enactment of new licensing laws and the creation of a "respectable" medical educational system. Also at this time, the concept of "scientific medicine" was brought to America. (Although Starr differed from Rothstein regarding the causes of the decline of the homeopathic and eclectic sectarian schools, he noted that Rothstein clearly documented the nineteenth century transition of medicine into a recognized professional class composed of both the minority sects and the orthodox school.)

This transition from conflict between the major sects resulted in the erosion of the implementation of the code of ethics, the cooperation among the sects to revive medical licensing standards, the admission of sectarian physicians to regular medical societies, and, ultimately, a structural reorganization of the AMA, which occurred between 1875 and 1903.[1,5]

Once the cooperation among the three medical views began, the medical class dominated by the regular school came fully into power. The homeopathic and eclectic schools of thought met their demise finally due to two significant events: (1) the rapid creation of new medical educational standards between 1900 and 1910, culminating in the publication of the famous "Flexner Report" (1910), and (2) the effective infusion of millions of dollars into selected allopathic medical schools by the newly created capitalistic philanthropic foundations, principally the Carnegie and Rockefeller foundations.

The Foundations

The impact of the monies from the Carnegie and Rockefeller foundations was clearly documented[7] and described in detail in Brown's *Rockefeller Medicine Men*.[8] The impact of the monies from these foundations, contributed to medical schools that met the AMA's views on medical education and philosophy, cannot be underestimated.

This process has been well documented.[1,7,9,10] As discussed by Burrows,[10] these educational reforms allowed the AMA to forge a new alliance with state legislators and push quickly for medical licensing designed to reward the educational and medical expertise of the newly orthodox "scientific medicine" and to the exclusion of all others.

Medical Education in Transition

Based on the rising example of scientific medicine and its necessary connection to research, the educational laboratory, and a more thorough scientific education as a preamble to medical practice, Harvard University (under the presidency of Charles Elliott) created a 4-year medical educational program in 1871. The primal modern medical educational curriculum was devised and set in motion more than 20 years later at Johns Hopkins University under the leadership of William Osler and William Welch, using the resources from the original endowment of the hospital and university from the estate of Johns Hopkins.[1]

Other schools followed suit. By the time the AMA set up its Council on Medical Education in 1904, it was made up of five members from the faculties of schools modeled on the Johns Hopkins prototype. This committee set out to visit and rate each of the 160 medical schools then in operation in the country. The ratings used were class "A" (acceptable), class "B" (doubtful), and class "C" (unacceptable).

Eighty-two schools received a class "A" rating, led by Harvard, Rush (Chicago), Western Reserve, the University of California and, notably, Johns Hopkins. Forty-six schools received a class "B" rating, and thirty-two a class "C" rating. The class "C" schools were mostly in rural areas, and many of them were proprietary in nature.

Flexner Report

Subsequent to the AMA ratings, the Council on Medical Education applied to the Carnegie Foundation to commission an independent report to verify its work. Abraham Flexner, a young, energetic, and noted educator, was chosen for this task by the Carnegie Foundation and accompanied by the secretary (Nathan Colwell, MD) of the Council on Medical Education, who participated in all of the committee site visits.

Flexner visited each of the 162 operating U.S. medical schools. The widely publicized *Flexner Report* put the nails in the coffins of all schools with class "C" ratings and many with class "B" ratings. Significantly, the educational programs of all but one eclectic school (in Cincinnati) and one homeopathic school (in Philadelphia) were eliminated by 1918.

The eclectic medical schools, in particular, were severely affected by the report. Griggs explained this effect as follows[2]:

Of the eight Eclectic schools, the Report declared that none had "anything remotely resembling the laboratory equipment which is claimed in their catalogs." Three of them were under-equipped;

the rest "are without exception filthy and almost bare. They have at best grimy little laboratories … a few microscopes, some bottles containing discolored and unlabeled pathological material, in an incubator out of commission, and a horrid dissecting room." The Report found them more culpable than a regular school for these inadequacies: "… the Eclectics are drug-mad; yet, with the exception of the Cincinnati and New York schools, they are not equipped to teach the drugs or drug therapy which constitutes their sole reason for existence."

The other regular schools that conducted homeopathic or eclectic programs had by that time phased them out in the name of "scientific medicine" (see also Haller[3]).

Pharmaceutical Industry

During this same time, the AMA, through several of its efforts, began a significant alliance with the organized pharmaceutical industry of the United States, shaping it in a manner acceptable to the allopathic profession.[1,9,11]

The New "Sects"

The period from 1890 to 1905 saw the rise of three new medical sects and several other smaller "irregular" schools that replaced those soon to pass from the scene. In Missouri, Andrew Taylor Still, originally trained as an orthodox practitioner, founded the school of medical thought known as "osteopathy" and in 1892 opened the American School of Osteopathy in Kirksville, Missouri. In 1895, Daniel David Palmer, originally a magnetic healer from Davenport, Iowa, performed the first spinal manipulation, which gave rise to the school he termed "chiropractic." He formally published his findings in 1910, after having founded a chiropractic school in Davenport, Iowa. In 1902, Lust founded the American School of Naturopathy in New York.

Although some of the following discussions are devoted to the schools of healing called osteopathy and chiropractic, only that portion of their histories related to the history of naturopathy is mentioned.[12] (A full study of osteopathic medicine in America may be found in *The D.O.'s* by Gevitz,[13] and a reasonable sketch of chiropractic medicine may be found in Kapling's chapter in *Alternative Medicine.*[12])

As noted by Starr,[1] these new sects, including Christian Science, formulated by Mary Baker Eddy,[14] either rose or fell on their own without ever completely allying with orthodox medicine. Starr theorized that these sects arose late enough that the orthodox profession and its political action arm, the AMA, had no need to ally with them and would rather battle with them publicly. This made these sectarian views separate and distinct from the homeopathic and eclectic schools.

THE FOUNDING OF NATUROPATHIC MEDICINE

Benedict Lust

Lust came to the United States in 1892 at the age of 23. He suffered from a debilitating condition in his late teens while growing up in Michelbach, Baden, Germany, and was sent by his father to undergo the Kneipp cure at Woerishofen. He stayed there from mid-1890 to early 1892; not only was he "cured" of his condition, but he also became a protégé of Kneipp. Dispatched by Kneipp to bring the principles of the Kneipp water cure to America, he emigrated to New York City.

By making contact in New York with other German Americans who were also becoming aware of the Kneipp principles, Lust participated in the founding of the first "Kneipp Society," which was organized in Jersey City, New Jersey, in October 1896.

Lust also attended the first organizational meeting (in mid-October 1896) of the Kneipp Society of Brooklyn. Subsequently, through Lust's organization and contacts, Kneipp Societies were founded in Boston; Chicago; Cleveland; Denver; Cincinnati; Philadelphia; Columbus; Buffalo and Rochester, New York; New Haven, Connecticut; San Francisco; New Mexico; and Mineola on Long Island, New York.

The members of these organizations were provided with copies of the *Kneipp Blatter* and a companion English publication Lust began to put out called *The Kneipp Water Cure Monthly*.

The first "sanatorium" using Kneipp's principles was organized in this country shortly before Lust's arrival. Charles Lauterwasser, an earlier student of Kneipp's who called himself a hydrothic physician and natural scientist, opened the Kneipp and Nature Cure Sanatorium in Newark, New Jersey, in 1891.

In 1895, the Brooklyn Light and Water-Cure Institute was established in Brooklyn, New York, by L. Staden and his wife Carola, both graduates of Lindlahr's Hygienic College in Dresden, Germany. According to their advertising, they specialized in natural healing, Kneipp water treatment, and Kuhne's and Preissnitz's principles (including diet cure, electric light baths [both white and blue], electric vibration massage, Swedish massage and movements, and Thure-brandt massage).

In 1895, Lust opened the Kneipp Water-Cure Institute in New York City, listing himself as the owner and Dr. William Steffens as the residing physician. At the same address (on 59th Street) in October of that year, Lust opened the first "Kneipp store." In the originating November 1896 edition of *The Kneipp Water Cure Monthly* and *Kneipp Blatter*, he advertised his store and sanitarium as personally authorized by Kneipp. In the first part of 1896, just before his organizing of various Kneipp Societies around the New York area, Lust returned to Woerishofen to study further with Kneipp.

Kneipp died in Germany, at Woerishofen, in June 1897. With his passing, Lust was no longer bound strictly to the principles of the Kneipp water cure. He had begun to associate earlier with other German-American physicians, principally Dr. Hugo R. Wendel (a German-trained *Naturarzt*), who began, in 1897, to practice in New York and New Jersey as a licensed osteopathic physician. In 1896, Lust entered the Universal Osteopathic College of New York, graduated in 1898, and became licensed as an osteopathic physician. In 1897, Lust became an American citizen.

Once he was licensed to practice as a health care physician in his own right, Lust began the transition toward the concept of "naturopathy." Between 1898 and 1902, when he adopted the term "naturopath," Lust acquired a chiropractic education and changed the name of his Kneipp store to Health Food Store (the original facility to use that name and concept in this country), specializing in providing organic foods and the materials necessary for drugless cures. He also began the New York School of Massage (listed as established in 1896) and the American School of Chiropractic, all within the same facility—Lust's Kneipp Institute.

Photographs of this facility taken between 1902 and 1907, when the facility moved to another location, show a five-story building listing "Benedict Lust—Naturopath, Publisher, Importer."

He returned to Germany in 1907 to visit with Dr. Baumgarten, Kneipp's medical successor at the Woerishofen facility, which was then run, in cooperation with Baumgarten, by the Reverend Prior Reily, the former secretary to Kneipp and his lay

successor at Woerishofen. As directed by Kneipp, Reily had completed, after Kneipp's death, Kneipp's master work *Das grosse Kneipp—Buch*. Lust maintained contact with the partnership of Reily and Baumgarten throughout the early part of the twentieth century.

In 1902, when he purchased and began using the term naturopathy and calling himself a "naturopath," Lust, in addition to his New York School of Massage and American School of Chiropractic, his various publications, and his operation of the Health Food Store, began to operate the American School of Naturopathy, all at the same 59th Street New York address.

By 1907, Lust's enterprises had grown sufficiently large that he moved them to a 55-room building. It housed the Naturopathic Institute, Clinic and Hospital; the American Schools of Naturopathy and Chiropractic; the now entitled Original Health Food Store; Lust's publishing enterprises; and New York School of Massage. The operation remained in this four-story building, roughly twice the size of the original facility, from 1907 to 1915.

From 1912 to 1914, Lust took a "sabbatical" from his operations to further his medical education. By this time he had founded his large estate-like sanitarium in Butler, New Jersey, known as "Yungborn" after the German sanitarium operation of Adolph Just.

In 1912 he attended the Homeopathic Medical College in New York, which, in 1913, granted him a degree in homeopathic medicine and, in 1914, he received his degree in eclectic medicine. In early 1914, Lust traveled to Florida and obtained an MD's license on the basis of his graduation from the Homeopathic Medical College and the Eclectic Medical College of New York City.

He founded another "Yungborn" sanitarium facility in Tangerine, Florida, and for the rest of his life, while continuing his publications, he engaged in active public lecturing. He also continued to maintain a practice in New York City and operated the sanitariums in Florida and New Jersey. His schools were operated primarily by Hugo R. Wendel.

From 1902, when he began to use the term naturopathy, until 1918, Lust replaced the Kneipp Societies with the Naturopathic Society of America. Then, in December 1919, the Naturopathic Society of America was formally dissolved due to its insolvency and Lust founded the American Naturopathic Association (ANA). Thereafter, 18 states incorporated the association.

In 1918, as part of his effort to replace the Naturopathic Society of America (an operation into which he invested a great deal of his funds and resources in an attempt to organize a naturopathic profession) and replace it with the ANA, Lust published the first *Universal Naturopathic Directory and Buyer's Guide* (a "yearbook of drugless therapy").

Although a completely new version was never actually published, despite Lust's announced intention to make this volume an annual publication, annual supplements were published in either *The Naturopath and Herald of Health* or its companion publication *Nature's Path* (which commenced publication in 1925). The *Naturopath and Herald of Health*, sometimes printed with the two phrases reversed, was published from 1902 to 1927, and from 1934 until after Lust's death in 1945.

This volume documented the merging of the German and American influences that influenced Lust in his development of the practice of naturopathy. The voluminous tome, which ran to 1416 pages, was dedicated to:

> *The memory of all those noble pioneers and discoverers who have died in the faith of Naturopathy, and to their courageous successors in the art of drugless healing, all of whom have suffered persecution for saving human lives that medical autocracy could not save, this work is respectfully dedicated by its editor Benedict Lust, N.D., M.D., "The Yungborn," Butler, New Jersey, U.S.A., April 1, 1918.*

Lust's introduction is reprinted here in its entirety to show the purpose of the directory and the status of the profession in the early 1900s:

> **Introduction**
> *To the Naturopathic Profession, the Professors of Natural Healing in all its branches, the Professors of Scientific Diet, Hydrotherapy, Heliotherapy, Electrotherapy, Neuropathy, Osteopathy, Chiropractic, Naprapathy, Magnetopathy, Phytotherapy, Exercise, Swedish Movements, Curative Gymnastics, Physical and Mental Culture, Balneopathy, and all forms of Drugless Healing, the Faculties of all Drugless Colleges, Institutions, Schools, and all Professors of Hygiene and Sanitation; Manufacturers of Naturopathic Supplies; Publishers of Health Literature, and Natural Healing Societies, GREETINGS:*
>
> *I have the honor to present to your consideration and goodwill, this Volume, No. 1, Year 1918-1919, of the Universal Naturopathic Directory, Year Book of Drugless Healing, and Buyers' Guide.*
>
> *For twenty-two years past, the need of a directory for Drugless Therapy has been felt. The medical world is in a condition of intense evolution at the present time. It is evolving from the Drugging School of Therapy to the Drugless School. People by the million have lost confidence in the virtues of Allopathy and are turning with joyful confidence to the Professions of Natural Healing until it has been estimated that there are at least forty thousand practitioners of Naturopathic healing in the United States.*
>
> *The motto that IN UNITY THERE IS STRENGTH is the foundation of the present enterprise.*
>
> *Hitherto, the drugless profession has lacked that prestige in the eyes of the public, which comes from the continuous existence of a big institution, duly organized and wielding the immense authority which is derived no less from organization and history than from the virtues of the principles that are held and practiced by such institutions. The public at large instantaneously respects an institution that is thoroughly organized and has its root earthed in history.*
>
> *The time has fully arrived when the drugless profession should no longer exist in the form of isolated units, not knowing one another and caring but little for such knowledge. Our profession has been, as it were, as sheep without a shepherd, but the various individuals that constitute this movement so pregnant with benefits to humanity, are now collected for the first time into a Directory and Year-Book of Drugless Healing, which alone will give immense weight and dignity to the standing of the individuals mentioned therein.*
>
> *Not only will the book add to the prestige of the practitioner in the eyes of his patients, but when the scattered members of our profession in every State desire to obtain legislative action on behalf of their profession and themselves, the appeal of such a work as our directory will, in the eyes of legislators, gain for them a much more respectful hearing than could otherwise be obtained.*

Now, for the first time, the drugless practitioner finds himself one of a vast army of professional men and women who are employing the most healthful forces of nature to rejuvenate and regenerate the world. But the book itself throws a powerful light upon every phase of drugless healing and annihilates time and distance in investigating WHO IS WHO in the realm of Drugless Therapy.

A most sincere effort has been made to obtain the name and address of every adherent of the Rational School of Medicine who practices his profession within the United States, Canada and the British Isles. It is impossible at this stage of Naturopathic history, which is still largely in the making, to obtain the name and address of every such practitioner. There were some who, even when appealed to, refused to respond to our invitation, not understanding the object of our work. Many of even the most intelligent members have refused to advertise their professional cards in our pages. But we can only attribute these drawbacks to the fact that every new institution that has suddenly dawned upon human intelligence will find that a certain proportion of people who do not understand the nature of the enterprise because the brain cells that would appreciate the benefits that are sought to be conferred upon them, are undeveloped, but a goodly proportion of our Naturopaths have gladly responded to the invitation to advertise their specialty in our columns. These, of course, constitute the brightest and most successful of our practitioners and their examples in this respect should be followed by every practitioner whose card does not appear in this book.

We take it for granted that every one of the forty thousand practitioners of Naturopathy is in favor of the enterprise represented by this Directory. This work is a tool of his trade and not to possess this book is a serious handicap in the race for success.

Here will be found an Index of by far the larger number of Naturopaths in the country arranged in Alphabetic, Geographic and Naturopathic sections. Besides this, there is a classified Buyers' Guide that gives immediate information regarding where you can find special supplies, or a certain apparatus, or a certain book or magazine, its name, and where it is published. The list of Institutions with the curriculum of each will be found exceedingly useful.

Natural healing, that has drifted so long, and, by reason of a lack of organization, has been made for so many years the football of official medicine, to be kicked by any one who thought fit to do so, has now arrived at such a pitch of power that it has shaken the old system of bureaucratic medicine to its foundations. The professors of the irrational theories of life, health and disease, that are looking for victims to be inoculated with dangerous drugs and animalized vaccines and serums, have begun to fear the growth of this young giant of medical healing that demands medical freedom, social justice and equal rights for the new healing system that exists alone for the betterment and uplifting of humanity.

I want every Professor of Drugless Therapy to become my friend and co-worker in the great cause to which we are committed, and those whose names are not recorded in this book should send them to me without delay. It will be of far greater interest and value to themselves to have their professional card included amongst those who advertise with us than the few dollars that such advertisement costs.

It will be noted that there are quite a number of Drugless Healers belonging to foreign countries (particularly those of the Western Hemisphere) represented in this Directory. The profession of medicine is not confined to any race, country, clime or religion. It is a universal profession and demands universal recognition. It will be a great honor to the Directory, as well as to the Naturopathic profession at large to have every Naturopathic practitioner, from the Arctic Circle to the furthest limits of Patagonia, represented in the pages of this immense and most helpful work.

I expect that the Directory for the year 1920 will be larger and even more important than the present Directory and that it will contain the names of thousands of practitioners that are not included in the present work.

The publication of this Directory will aid in abolishing whatever evils of sectarianism, narrow-mindedness and lack of loyalty to the cause to which we are devoted, that may exist. That it will promote a fraternal spirit among all exponents of natural healing, and create an increase of their prestige and power to resist the encroachments of official medicine on their constitutional rights of liberty and the pursuit of happiness, by favorably influencing Legislators, Law courts, City Councils and Boards of Health everywhere, is the sincere belief of the editor and publisher.

Having introduced the volume, Lust leads off with his article entitled "The principles, aim and program of the nature cure system."

Again, this relatively brief article is reproduced here in its entirety, so that one can see the merging of influences:

The principles, aim and program of the nature cure system

Since the earliest ages, Medical Science has been of all sciences the most unscientific. Its professors, with few exceptions, have sought to cure disease by the magic of pills and potions and poisons that attacked the ailment with the idea of suppressing the symptoms instead of attacking the real cause of the ailment.

Medical science has always believed in the superstition that the use of chemical substances which are harmful and destructive to human life will prove an efficient substitute for the violation of laws, and in this way encourages the belief that a man may go the limit in self indulgences that weaken and destroy his physical system, and then hope to be absolved from his physical ailments by swallowing a few pills, or submitting to an injection of a serum or vaccine, that are supposed to act as vicarious redeemers of the physical organism and counteract life-long practices that are poisonous and wholly destructive to the patient's well-being.

From the earliest ages to the present time, the priests of medicine have discovered that it is ten times easier to obtain ten dollars from a man by acting upon his superstition, than it is to extract one dollar from him, by appealing to reason and common sense. Having this key to a gold mine within their grasp, we find official medicine indulging at all times in the most blatant, outrageous, freakish and unscientific methods of curing disease, because the methods were in harmony with the medical prestige of the physician.

Away back in pre-historic times, disease was regarded as a demon to be exorcized from its victim, and the medicine man of his tribe belabored the body of his patient with a bag in which rattled bones and feathers, and no doubt in extreme cases the tremendous faith in this process of cure that was engendered in the mind of the patient really cured some ailments for which

mental science and not the bag of bones and feathers should be given credit.

Coming down to the middle ages, the Witches' Broth—one ingredient of which was the blood of a child murderer drawn in the dark of the moon—was sworn to, by official medicine, as a remedy for every disease.

In a later period, the "docteur a la mode," between his taking pinches of snuff from a gold snuff box, would order the patient bled as a remedy for what he denominated spirits, vapors, megrims, or miasms.

Following this pseudo-scientific diagnosis and method of cure, came the drugging phase in which symptoms of disease were unmercifully attacked by all kinds of drugs, alkalis, acids and poisons which were supposed, that by suffocating the symptoms of disease, by smothering their destructive energy, to thus enhance the vitality of the individual. All these cures have had their inception, their period of extensive application, and their certain desuetude. The contemporary fashion of healing disease is that of serums, inoculations and vaccines, which, instead of being an improvement on the fake medicines of former ages are of no value in the cure of disease, but on the contrary introduce lesions into the human body of the most distressing and deadly import.

The policy of expediency is at the basis of medical drug healing. It is along the lines of self-indulgence, indifference, ignorance and lack of self-control that drug medicine lives, moves and has its being. The sleeping swineries of mankind are wholly exploited by a system of medical treatment, founded on poisonous and revolting products, whose chemical composition and whose mode of attacking disease, are equally unknown to their originators, and this is called "Scientific medicine."

Like the alchemist of old who circulated the false belief that he could transmute the baser metals into gold, in like manner the vivisector claims that he can coin the agony of animals into cures for human disease. He insists on cursing animals that he may bless mankind with such curses.

To understand how revolting these products are, let us just refer to the vaccine matter which is supposed to be an efficient preventive of smallpox. Who would be fool enough to swallow the putrid pus and corruption scraped from the foulest sores of smallpox that has been implanted in the body of a calf? Even if any one would be fool enough to drink so atrocious a substance, its danger might be neutralized by the digestive juices of the intestinal tract. But it is a far greater danger to the organism when inoculated into the blood and tissues direct, where no digestive substances can possibly neutralize its poison.

The natural system for curing disease is based on a return to nature in regulating the diet, breathing, exercising, bathing and the employment of various forces to eliminate the poisonous products in the system, and so raise the vitality of the patient to a proper standard of health.

Official medicine has in all ages simply attacked the symptoms of disease without paying any attention to the causes thereof, but natural healing is concerned far more with removing the causes of disease, than merely curing its symptoms. This is the glory of this new school of medicine that it cures by removing the causes of the ailment, and is the only rational method of practicing medicine. It begins its cures by avoiding the uses of drugs and hence is styled the system of drugless healing. It came first into vogue in Germany and its most famous exponents in that country were Priessnitz, Schroth, Kuhne, Kneipp, Rickli, Lahmann, Just, Ehret, Engelhardt, and others.

In Sweden, Ling and others developed various systems of mechano-therapy and curative gymnastics.

In America, Palmer invented Chiropractic; McCormick, Ophthalmology. Still originated Osteopathy; Weltmer, suggestive Therapeutics. Lindlahr combined the essentials of various natural methods, while Kellogg, Tilden, Schultz, Trall, Lust, Lahn, Arnold, Struch, Havard, Davis, Jackson, Walters, Deininger, Tyrell, Collins and others, have each of them spent a lifetime in studying and putting into practice the best ideas of drugless healing and have greatly enlarged and enriched the new school of medicine.

Life maltreated by allopathy

The prime object of natural healing is to give the principle of life the line of least resistance, that it may enable man to possess the most abundant health.

What is life?

The finite mind of man fails to comprehend the nature of this mysterious principle. The philosopher says "Life is the sum of the forces that resist death," but that definition only increases its obscurity. Life is a most precious endowment of protoplasm, of the various combinations of oxygen, hydrogen, carbon and nitrogen, and other purely mineral substances in forming organic tissues. As Othello says, referring to Desdemona's life, which he compares to the light of a candle—

"If I quench thee thou flaming minister,

I can thy former light restore

Should I repent me; but once put out THY light,

I know not whence is that Promethean heat

That can thy light relume."

The spark of life flickers in the sockets of millions and is about to go out. What system of medicine will most surely restore that flickering spark to a steady, burning flame?

Will [it be] the system that employs poisonous vaccines, serums and inoculations, whose medical value has to be supported by the most mendacious statements, and whose practitioners are far more intent on their emoluments and fame, than they are in the practice of humanity?

The Allopathic system, which includes nine tenths of all medical practitioners, is known by its fruits, but it is an appalling fact that infant mortality, insanity, heart disease, arteriosclerosis, cancer, debility, impoverished constitutions, degeneracy, idiocy and inefficiency have enormously increased, particularly during the last twenty-five years, that is, during the regime of inoculations, serums and vaccines.

Naturopathy, on the other hand, so far as it has been developed, and so far as official medicine will allow it to act, leaves no such trail of disease, disaster and death behind it. Natural healing is emancipation from medical superstition, ignorance and tyranny. It is the true Elixir of Life.

The Allopaths have endeavored to cure sick humanity on the basis of the highly erroneous idea that man can change the laws of nature that govern our being, and cure the cause of disease by simply ignoring it. To cure disease by poisoning its symptoms is medical manslaughter.

Dr. Schwenninger of Germany says: "We are suffering under the curse of the past mistakes of our profession. For thousands of years medical doctors have been educating the public into the false belief that poisonous drugs can give health. This belief has become in the public mind such a deep-seated superstition, that those of us who know better and who would like to adopt more sensible, natural methods of cure, can do so only at the peril of losing practice and reputation.

"The average medical man is at his best but a devoted bigot to this vain school-craft, which we call the Medical Art and which alone in this age of science has made no perceptible progress since the days of its earliest teachers. They call it recognized science! Recognized ignorance! The science of to-day is the ignorance of to-morrow. Every year some bold guess lights up as truth to which but the year before the schoolmen of science were as blind as moles."

And Dr. O.W. Holmes, Professor of Anatomy in Harvard University, states: "The disgrace of medicine has been that colossal system of self-deception, in obedience to which mines have been emptied of their cankering minerals, entrails of animals taxed for their impurities, the poison bags of reptiles drained of their venom, and all the inconceivable abominations thus obtained thrust down the throats of human beings, suffering from some fault of organization, nourishment, or vital stimulation."

And these misguided drug doctors are not only not ashamed of their work, but they have induced subservient legislators to pass laws that perpetuate the age-long scandal of allopathic importance, and the degenerative influence of the poisons, and to actually make it a crime on the part of nature doctors to cure a man of his ailment. The brazen effrontery of these medical despots has no limits. They boast of making the State legislators their catspaw in arresting, fining and imprisoning the professors of natural healing for saving human life.

Legislators have no right to sit in judgment over the claims of rival schools of healing. They see tens of thousands of sick people go down to their graves by being denied the cures that the employers of nature's forces alone can give them. It is their business to provide for the various schools of medicine a fair field and no favor.

A citizen has an inalienable right to liberty in the pursuit of happiness. Yet the real saviors of mankind are persecuted by the medical oligarchy which is responsible for compulsory vaccination, compulsory medical inspection of public school children, and the demands for State and Federal departments of health, all for the ostensible good of the people, but in reality for the gain of the Medical Trust.

The naturopaths

The Naturopaths are desirous of freedom for all schools of medicine. They are responsible practitioners who are willing to be examined by an impartial council, appointed by and acting for the State, who will testify to the life and character of every drugless physician before he is entitled to practice medicine. Not one invidious discrimination should be made between the different schools of medicine. The state should see to it that each school should have a full opportunity to do its best for the up-lifting of its citizens.

The program of naturopathic cure

1. ELIMINATION OF EVIL HABITS, or the weeds of life, such as over-eating, alcoholic drinks, drugs, the use of tea, coffee and cocoa that contain poisons, meat eating, improper hours of living, waste of vital forces, lowered vitality, sexual and social aberrations, worry, etc.
2. CORRECTIVE HABITS. Correct breathing, correct exercise, right mental attitude. Moderation in the pursuit of health and wealth.
3. NEW PRINCIPLES OF LIVING. Proper fasting, selection of food, hydropathy, light and air baths, mud baths, osteopathy, chiropractic and other forms of mechano-therapy, mineral salts obtained in organic form, electropathy, heliopathy, steam or Turkish baths, sitz baths, etc.

Natural healing is the most desirable factor in the regeneration of the race. It is a return to nature in methods of living and treatment. It makes use of the elementary forces of nature, of chemical selection of foods that will constitute a correct medical dietary. The diet of civilized man is devitalized, is poor in essential organic salts. The fact that foods are cooked in so many ways and are salted, spiced, sweetened and otherwise made attractive to the palate, induces people to over-eat, and over eating does more harm than under feeding. High protein food and lazy habits are the cause of cancer, Bright's disease, rheumatism and the poisons of auto-intoxication.

There is really but one healing force in existence and that is Nature herself, which means the inherent restorative power of the organism to overcome disease. Now the question is, can this power be appropriated and guided more readily by extrinsic or intrinsic methods? That is to say, is it more amenable to combat disease by irritating drugs, vaccines and serums employed by superstitious moderns, or by the bland intrinsic congenial forces of Natural Therapeutics, that are employed by this new school of medicine, that is Naturopathy, which is the only orthodox school of medicine? Are not these natural forces much more orthodox than the artificial resources of the druggist? The practical application of these natural agencies, duly suited to the individual case, are true signs that the art of healing has been elaborated by the aid of absolutely harmless, congenial treatments, under whose ministration the death rate is but five per cent of persons treated as compared with fifty per cent under the present allopathic methods.

The Germanic Influence

The philosophical origins of naturopathy were Germanic. The most significant influences, except those of Russell Trall, the osteopathic concepts of A.T. Still (at this time strictly the correction of spinal lesions by adjustment), and the chiropractic principles of D.D. Palmer, were originally Germanic. (This was well established in the January 1902 editorial in *Water Cure Monthly*.)

The specific influences on which Lust drew for his work, in order of their chronological contributions to the system of naturopathy, are the following:

1. Vincent Preissnitz (1799–1851)
2. Johann Schroth (1798–1856)
3. Father Sebastian Kneipp (1821–1897)
4. Arnold Rickli (1823–1926)

5. Louis Kuhne (c. 1823–1907)
6. Henry Lahman (no dates known)
7. F.E. Bilz (1823–1903)
8. Adolph Just (1859–1939).

Also of note were Theodor Hahn and T. Meltzer, who, in the 1860s, were well known for their work in the movement called, in German, *Naturatz* or "naturism."

In photographs accompanying his article "The principles, aim and program of the nature cure system," Lust described each of these thinkers as follows:

1. *VINCENT PREISSNITZ, of Graefenberg, Silesia. Founder of Hydropathy. Born October 4, 1799. A pioneer Naturopath, prosecuted by the medical authorities of his day, and convicted of using witchcraft, because he cured his patients by the use of water, air, diet and exercise. He took his patients back to Nature—to the woods, the streams, the open fields—treated them with Nature's own forces and fed them on natural foods. His fame spread over the whole of Europe, and even to America. His cured patients were numbered by the thousands. The Preissnitz compress or bandage is in the medical literature. Preissnitz is no more, but his spirit lives in every true Naturopath.*
2. *JOHANN SCHROTH, a layperson, not described in Lust's directory but often talked of in later works and prominently mentioned for his curative theories in Bilz's master work, The Natural Method of Healing. Schroth smashed his right knee in an accident with a horse and it remained stiff in spite of repeated medical treatment. At last, a priest told Schroth that Preissnitz's methods might help, and Schroth decided to give them a try. In order to avoid frequent changing of the packs that were directed by Preissnitz, he placed several packs on top of one another, wrapping the whole portion with a woolen cloth. He left this pack on the injured knee for several hours and produced a moist heat which he theorized to cause the poisonous toxins to dissolve and be swept away. These packs are still used as part of the "Schroth cure" and have reportedly become famous for their blood-cleansing effect. (From an article in the March 1937 Naturopath and Herald of Health by Dr. T.M. Schippel.) As noted by Bilz, the Schroth cure, called by Bilz "the regenerative treatment," was developed for treatment of chronic diseases through the use of an extreme diet following total fasting by withdrawing of all food and drink and then the use of totally dry grain products and the eventual reintroduction of fluids.*
3. *FATHER SEBASTIAN KNEIPP, of course, is much described and the photos include one of Kneipp lecturing to the multitudes at Wandelhale at Woerishofen, attending Pope Leo XIII in 1893, noting this is the only consultation on health care matters that Kneipp ever consented to outside of Woerishofen, though many famous and aristocratic individuals desired his counsel, and a picture of Kneipp with the Archdukes Joseph and Francis Ferdinand of Austria walking barefoot in new-fallen snow for purposes of hardening the constitution. It was noted that the older Archduke was cured by Kneipp of Bright's disease in 1892, and it noted that the Archduke Joseph, in appreciation of this cure, donated a public park in the town of Woerishofenat a cost of $150,000 florens. The Archduke Francis Ferdinand, the son of Archduke Joseph, was the individual whose murder precipitated World War I. There is a further picture of Kneipp surrounded by "Doctors" from different parts of the world while he gave consultation to numerous patients.*
4. *ARNOLD RICKLI, founder of the light and light and air cures (atmospheric cure). Dr. Rickli was one of the foremost exponents of natural living and healing. In 1848, he established at Veldes, Krain, Austria, the first institution of light and air cure or as it was called in Europe the "atmospheric cure." In a limited way (rather very late) his ideas have been adopted by the medical profession in America for the cure of consumption. He was an ardent disciple of the vegetarian diet and exemplified the principles of natural living in his own life. The enclosed photo shows him at the age of 97, when he was still active and healthy. He has since passed on, but his work still lives as a testimonial of his untiring efforts. He was the founder and for over 50 years the President of the National Austrian Vegetarian Association.*
5. *LOUIS KUHNE wrote, in 1891, The New Science of Healing, the greatest work of basic principles in natural healing. In the tradition of Natural Healing and prevention, Kuhne has been described as one who "… advocated sun, steam baths, a vegetarian diet, and whole-wheat bread … in these relatively early days." His renowned work constitutes the only true scientific philosophy for the application of all Drugless Methods. He was the first to give to the world the comprehensible idea of pathology and the first to proclaim the doctrine of the "unity of cure." His book Facial Expression gives the means of diagnosing a patient's pathological condition and determining the amount and location of the systemic encumbrance. He is the founder and first Master of Naturopathy.*
6. *DR. H. LAHMAN. When the University of Leipzig expelled H. Lahman for his spreading medical sedition among the students, it added a staunch advocate to natural healing. Dr. Lahman finished his medical education in Switzerland and returned to Germany to refute in practice the false ideas of medical science. He later founded the largest Nature Cure institution in the world at Weisser Hirsch, near Dresden, Saxony. He was a strong believer in the "Light and Air" cure and constructed the first appliances for the administration of electric light treatment and baths. He was the author of several books on Diet, Nature Cure and Heliotherapy. As noted in Other Healers, Other Cures: "Heinrich Lahmann came along to stress no salt on foods and no water with meals … "[15] His works on diet are authoritative and his "nutritive salts theory" forms the basis of rational dietetic treatment. This work has but recently come to light in America, and progressive dietitians are forsaking their old, worn-out, high protein, chemical and caloric theories for the "organic salts theory." Carque, Lindlahr, McCann, and other wide awake food scientists have adopted it as a basis for their work. Dr. Lahman was a medical nihilist. He denounced medicine as unscientific and entirely experimental in its practice and lived to prove the saneness of his ideas as evidenced by his thousands of cured patients.*
7. *PROFESSOR F.E. BILZ. That real physicians are born, not made, is well illustrated in the case of Dr. Bilz, who achieved his first success in healing as a lay practitioner. As a mark of gratitude, a wealthy patient presented him with land and a castle in which to found a Nature Cure sanitarium.… The Bilz institution at Dresden-Rdebeul, Germany, became world renowned and was long considered*

the center of the Nature Cure movement. Professor Bilz is the author of the first Naturopathic encyclopedia, The Natural Method of Healing, which has been translated into a dozen languages, and in German alone has run into 150 editions. He has written many works on Nature Cure and Natural Life, among them being The Future State, in which he predicted the present World War, and advocated a federation of nations as the only logical solution of international problems.

8. *ADOLPH JUST, famous author of Return to Nature and founder of original "Yungborn" in Germany.*

Both Adolph Just's *Return to Nature* and Louis Kuhne's *The Natural Science of Healing* were translated into English by Lust and released through his publication house.

The Convergence with American Influences

The Universal Naturopathic Directory was truly eclectic in its compilation and composition. Besides the Lust articles the volume included: "How I became acquainted with nature cure" by Henry Lindlahr, MD, ND (which was reproduced in large part in the introduction to volume 1 of Lindlahr[16]); "The nature cure" by Carl Strueh, MD, ND; "Naturopathy" by Harry E. Brook, ND; "The present position of naturopathy and allied therapeutic measures in the British Isles" by Allen Pattreiouex, ND; "Why all drugless methods?" by Per Nelson; and "Efficiency in drugless healing" by Edward Earle Purinton (a reprint of the 1917 publication, referred to earlier, which was composed of a series of articles published in *The Herald of Health and Naturopath* between August 1914 and February 1916).

The volume also contained Louis Kuhne's "Neo-naturopathy (the new science of healing)" in the first publication of the translation by Lust, and articles on electrotherapy, neuropathy, dietology, chiropractic, mechanotherapy, osteopathy, phytotherapy, apyrtropher, physical culture, optometry, hydrotherapy, orthopedics, pathology, natural healing and living, astroscopy, phrenology, and physiology—all of which were specially commissioned for the directory from practitioners and authors considered expert in these subjects.

Also included was a national directory of drugless physicians in alphabetical order, geographically arranged and itemized by profession; biographical notes on American contributors of note; the naturopathic book catalog; a guide to natural healing and natural life books and periodicals; a classified list of medical works; a series of book reviews; a buyer's guide for naturopathic supplies; and, in addition to extensive indexes, a "parting word" by Lust.

The volume contained numerous advertisements for naturopathic schools, sanitariums, and individual practices, and it closed with the following note:

This, then, completes Volume 1 of the Naturopathic Directory, Drugless Yearbook and Buyer's Guide for the years 1918 and 1919.

Into it, has been placed the conscientious labor of many willing hearts, hands and minds. It is their contribution to the noble cause of natural healing. It will stand as a monument to their endeavors, as well as a memorial to the great souls, the fathers of natural healing, who have passed on.

Let this, then, herald a new era—the era wherein man shall recognize the omniscience of Nature, and shall profit through conforming to her laws.

In the biographical sections, it is apparent that Lust owed a great deal of the feeling of camaraderie in the nature cure movement to some varied American practitioners. The most prominent of these had their biographical sections contained in the 1918 directory. Two of them deserve specific note and attention: Palmer and Still.

Lust met A.T. Still in 1915 in Kirksville, MO, shortly before Still's death. From their meetings, Lust noted later in the *Naturopath and Herald of Health* (June 1937) that Still believed that osteopathy by "compromising with medicine is doomed as the school that could have incorporated all the natural and biological healing arts." Lust wanted naturopathy to fill this void.

Lust also had lengthy acquaintance with B.J. Palmer (the son of D.D. Palmer, the founder of chiropractic), who, following in his father's footsteps, put Davenport, Iowa, and the Palmer Chiropractic College on the map.

Lust also became connected with Henry Lindlahr, MD, ND, of Chicago (as noted in the autobiographical sketch contained in the directory[17] and reprinted in volume 1 of Lindlahr[16]). Lindlahr was a rising businessman in Chicago with all the bad habits of the "gay nineties" era. In his 30s, he became chronically ill. He had gone to the orthodox practitioners of his day and received no relief.

Then, he was exposed to Schroth's works, and in following them began to feel somewhat better. Subsequently, he liquidated all his assets and went to a German sanitarium to be cured and to learn nature cure. He returned to Chicago and enrolled in the Homeopathic/Eclectic College of Illinois. In 1903, he opened a sanitarium, which included a residential sanitarium, located in Elmhurst, Illinois, a "transient" clinic (office) on State Street in Chicago, and "Lindlahr's Health Food Store."

Shortly thereafter. he founded the Lindlahr College of Natural Therapeutics, which included hospital internships at the sanitarium. The institution became one of the leading naturopathic colleges of the day. In 1908, he began to publish *Nature Cure Magazine* and began publishing his series of *Philosophy of Natural Therapeutics*, with volume 1 ("Philosophy") in 1918. This was followed by volume 2 ("Practice") in 1919, volume 3 ("Dietetics"; republished with revisions as originally published in 1914), and, in 1923, volume 6 ("Iridiagnosis"). The intended volumes 4 and 5 were in production at the time of Lindlahr's death in 1927. As described in *Other Healers, Other Cures*[15]:

Henry Lindlahr, another American, is remembered for his conviction that disease did not represent an invasion of molecules, but the body's way of healing something. In other words, he viewed symptoms as a positive physiological response—proof that the body is fighting whatever's wrong. Accordingly, a fever is a "healthy" sign and one should be let alone, unless it is dangerously high, of course.

The impact of all these gentlemen on the development of naturopathy in America, under Lust's guidance, was profound.

From these beginnings, the naturopathic movement gathered strength and continued to grow through the 1920s and 1930s, having a major impact on natural healing and natural lifestyle in the United States.

Along the way, Lust was greatly influenced by the writings of John H. Tilden, MD (largely published between 1915 and 1925). Tilden was originally a practicing physician in Denver who became disenchanted with orthodox medicine and began to rely heavily on dietetics and nutrition, formulating his theories of "auto-intoxication" (the effect of fecal matter remaining too long in the digestive process) and "toxemia."

Lust was also greatly influenced by Elmer Lee, MD, who became a practicing naturopath about 1910 and whose movement was called the "hygienic system," following the earlier works of Russell Trall. Lee published *Health Culture* for many years.

In addition to John Tilden, MD, and Elmer Lee, MD, another medical doctor, John Harvey Kellogg, MD, who turned to more nutritionally based natural healing concepts, was greatly respected by Lust. Kellogg was renowned through his connection with the Battle Creek Sanitarium. The sanitarium itself was originally founded in the 1860s as a Seventh Day Adventist institution designed to perpetuate the Grahamite philosophies of Sylvester Graham and William Alcott. The sanitarium was on the verge of being closed, however, due to economic failure, when in 1876, Kellogg, a new and more dynamic physician-in-chief, was appointed.

Kellogg, born in 1852, was a "sickly child" who, at the age of 14, ran across the works of Graham and converted to vegetarianism. At the age of 20, he studied for a term at Trall's Hygio-Therapeutic College and then earned a medical degree at New York's Bellevue Medical School. He maintained an affiliation with the regular schools of medicine during his lifetime, due more to his practice of surgery than his beliefs in the area of health care.[4]

Kellogg designated his concepts, which were basically the hygienic system of healthful living, "biologic living." Principally, Kellogg defended vegetarianism, attacked sexual misconduct and the evils of alcohol, and was a prolific writer through the late nineteenth century and early twentieth century. He produced a popular periodical, *Good Health*, which continued in existence until 1955. When Kellogg died in 1943 at the age of 91, he had had more than 300,000 patients through the Battle Creek Sanitarium (which he had had renamed from Western Health Reform Institute shortly after his appointment in 1876), including many celebrities, and the "San" became nationally well known.

Kellogg, along with Tilden and Elie Metchnikoff (director of the prestigious Pasteur Institute and winner of the 1908 Nobel Prize for a contribution to immunology), wrote prolifically on the theory of auto-intoxication. Kellogg, in particular, felt that humans in the process of digesting meat, produced various intestinal self-poisons that contributed to auto-intoxication.

As a result, Kellogg became a near fanatic on the subject of helping humans return to a more healthy, natural state by returning to the naturally designed usage of the colon. He felt that the average modern colon was devitalized by the combination of sedentary living, the custom of sitting rather than squatting to defecate, and the modern civilized habit of ignoring "nature's call" out of an undue concern for politeness. Further, Kellogg concentrated on the fact that the modern diet had insufficient bulk and roughage to stimulate the bowels to proper action.

Kellogg was also extremely interested in hydrotherapy. In the 1890s, he established a laboratory at the San to study the clinical applications of hydrotherapy. This led, in 1902, to his writing *Rational Hydrotherapy*. The preface espoused a philosophy of drugless healing that came to be one of the bases of the hydrotherapy school of medical thought in America.

Tilden, as mentioned, was of a similar mind. He must have been to have provided natural health care literature with his 200-plus page dissertation entitled "constipation," with a chapter devoted to the evils of not responding when nature called.

This belief in the "evils" drawing away from the natural condition of the colon was extremely important to Kellogg's work.[4] Because of Lust's interest, Kellogg's *The New Dietetics* (1921) became one of the bibles of naturopathic literature.[18]

Lust was also influenced by the works of Sidney Weltmer, the father of "suggestive therapeutics." The theory behind Professor Weltmer's work was that whether it was the mind or the body that first lost its grip on health, the two were inseparably related. When the problem originated in the body, the mind nonetheless lost its ability and desire to overcome the disease because the patient "felt sick" and consequently slid further into the diseased state. Alternatively, if the mind first lost its ability and desire to "be healthy" and some physical infirmity followed, the patient was susceptible to being overcome by disease.

Weltmer's work dealt specifically with the psychological process of desiring to be healthy. Lust enthusiastically backed Weltmer's work and had him appear on the programs at various annual conventions of the American Naturopathic Association (which commenced after its founding in 1919).

Lust was also personal friends with and a deep admirer of Bernarr MacFadden.[19] MacFadden was the founder of the "physical culture" school of health and healing, also known as "physcultopathy." This school of healing gave birth across the country to gymnasiums at which exercise programs, designed to allow the individual man or woman to maintain the most perfect state of health and human condition possible, were developed and taught.[4] *Other Healers, Other Cures* described it as follows[15]:

> *The next Naturopathic star, after Kellogg, was Bernarr MacFadden, the physical culturist who built a magazine-publishing empire (his first magazine was Physical Culture founded in 1898). MacFadden proselytizes for exercise and fresh vegetables, hardly eccentric notions. But his flamboyant efforts to publicize them and his occasional crack-pot ideas (like freezing the unemployed, then thawing them out when the Depression was over) alienated many people. Still, he was his own best advertisement. He fathered nine children by four wives and was parachuting from planes in his 80s. One of MacFadden's admirers was that arch-foe of the medical profession, George Bernard Shaw, the longevous eccentric in his own right …*

Lust was also interested in, and helped to publicize, "zone therapy," originated by Joe Shelby Riley, DC, a chiropractor based in Washington, D.C., and one of the early practitioners of "broad chiropractic." Zone therapy was an early forerunner of acupressure as it related "… pressures and manipulations of the fingers and tongue, and percussion on the spinal column, according to the relation of the fingers to certain zones of the body. …"[17]

Several other American drugless healers contributed to a broad range of "-opathies" that Lust merged into his growing view of naturopathy as the eclectic compilation of methods of natural healing. The *Universal Directory* also contained a complete list of osteopaths and chiropractors as drugless healers within the realm of Lust's view of naturopathic theory. His other significant compatriots at the time of the publication of the directory were Carl Stueh, described by Lust as "one of the first medical men in this country who gave up medicine and operation for natural healing"; F.W. Collins, MD, DO, DC, an early graduate of the American School of Naturopathy (1907) who went on to graduate from the New Jersey College of Osteopathy (1909) and the Palmer School of Chiropractic (1912); another "broad chiropractor," Anthony Matijaca, MD, ND, DO, the naturopathic resident expert in electrotherapy and an associate editor of the *Herald and Health Naturopath* (the inverted name of the Lust journal at the time of the directory); and Carl Schultz, ND, DO, MD, president and general manager of the Naturopathic Institute and Sanatorium of California, essentially the second school in the country to pursue the education of physicians under the name of "naturopathy."

In *Inner Hygiene: Constipation and the Pursuit of Health in Modern Society*, Whorton[20] offered his first assessments of the work of Lust as it related to the emergence of naturopathy in the early twentieth century:

> *Most of the drugless clan also identified themselves as practitioners of naturopathy, a system of practice that grew out of hydropathy, as well as German water-cure and nature-cure traditions. Organized in the late 1890s under the leadership of German immigrant Benedict Lust, naturopathy sought to cure the full scope of human ills with natural agents (herbs, water, air, sunlight, electricity, massage, and others), agents that supported and stimulated the body's own healing mechanisms.*

In his extensive assessments of Lust's work and writings in *Nature Cures: the History of Alternative Medicine in America*, Whorton[21] attempted to put the philosophical development of naturopathy in a reasonable historical context:

> *However much a dreamer Lust was in some respects, he was an insightful realist in others. He was correct in believing that simply giving nature support as it ran its course was the best one could do with many diseases in his day. He was correct in seeing self-abuse as the source of much physical, and emotional, suffering and attacked it with an ardor that MDs could not bring to the task until nearly a century later. Recent medical lamentations over the evils of smoking, sexual promiscuity, and other risky behaviors adopted in the thoughtless chase after pleasure have nothing on Lust's jeremiads …*
>
> *Lust was right in reprimanding allopaths for focusing so strongly on disease as to lose sight of the importance of promoting health. He was right in appreciating the need to "individualize" the treatment of each patient—and in seeing patient self-responsibility as part of that individualization.*

EARLY TWENTIETH-CENTURY MEDICINE

The Metamorphosis of Orthodox Medicine

Naturopathy's formative years, and in some respects its halcyon days, were from 1900 to 1917. In many jurisdictions modern licensing laws were not yet in effect, so varied schools of healing were openly practiced. By 1920, however, the American world of medicine had undergone a sharp transition, culminating in four decades of change.

A look at the structure of early medical care in the United States is instructive, even as practiced and dominated by the orthodox school, when noting the changes that occurred between 1875 and 1920.

In 1875, the following was descriptive of American medical practice:

- The practice, even in urban areas, sent the doctor to the patient; the "house call" was the norm.
- There was little modern licensing regulation.
- Hospitals were charitable institutions where persons too poor to otherwise receive health care were usually sent when ill.
- The AMA, although formed in 1846, and generally representative of the professional goals of the regular or orthodox school of medicine, had scarcely begun to make any political inroads at all.
- Medical schools required little or no college education for entrance and were largely apprenticeship based and proprietary in nature, having changed little throughout the century.
- Although some doctors had begun to specialize, to do so was far from the norm. The major recognized specialties were surgery, obstetrics, and gynecology.
- Many different types of doctors existed, and society's reaction to of the profession neither recognized specific expertise nor necessarily rewarded professionals in medical practice well.
- Although the orthodox school made up roughly 80% of professional medical practitioners, the homeopaths and the eclectics were visible and respected in their own communities for their abilities and expertise, and much of the public relied on other "irregular" practitioners.

By comparison, in 1920, a total metamorphosis of the medical profession had occurred:

- By 1920, practices had become office oriented and clinic oriented.
- Modern licensing principles had become fully developed, and physicians and surgeons were licensed in all jurisdictions. Most other health care providers had some licensing restrictions placed on them, if they were recognized at all.
- Due largely to the introduction into surgery of the practice of antiseptic techniques and aseptic procedures and a correspondent decline in operative mortality, institutional care in the hospital became increasingly accepted. Also, clinical pathology and diagnostic laboratory procedures had become well developed, and the hospital had become a major training and clinical research facility that was generally more acceptable to the patient.
- The AMA was approaching the peak of its political power, having exercised, through its Council on Medical Education and its Council of Pharmacy and Chemistry, major effects on medical schools and the pharmaceutical industry.
- The transition to research- and education-based medical schools, instead of practitioner apprenticeships and proprietary education, had become complete. All recognized medical schools had a 4-year curriculum, with an undergraduate degree or substantial undergraduate study required as a prerequisite. In addition, most schools, in conjunction with most licensing statutes, required a year's internship.
- Specialization was becoming well developed, and the number of specialty groups had increased considerably. This would continue through the 1930s and into the early 1940s.
- Professional authority and autonomy had undergone a substantial transition, and the allopathic physician was now recognized as the medical expert.
- By 1922, the last eclectic school was on the verge of closure, and in the early 1930s, the last of the homeopathic schools in the United States was also on the verge of closure. The influence of these sects on orthodox medicine had dwindled to almost nothing. Naturopaths and other alternative health care practitioners had adopted the areas of expertise previously considered the territory of homeopaths and eclectics.

The Halcyon Years of Naturopathy

In 1924 Morris Fishbein succeeded George Simmons as editor of the *Journal of the American Medical Association (JAMA)*. Fishbein had joined the editorial staff of *JAMA* under Simmons immediately after his graduation from Chicago's Rush Medical School in 1913. Campion pointed out the following[9]:

> *Over the years, Fishbein not only established himself as the gifted editor of the most widely read medical journal in the United States; he also learned how to extend his editorial position, how to project his opinions nationwide. He became, as the saying*

went in those years, a "personality." TIME referred to him as "the nation's most ubiquitous, the most widely maligned, and perhaps most influential medico."

In addition to his development of *JAMA* as an editorial and personal voice, Fishbein also continually railed against "quackery." Lust, among others, including MacFadden, became Fishbein's epitome of quackery. When MacFadden became a wealthy man, after his publishing company included popular magazines like *True Confessions* and *True Detective*, he began campaigning for the 1936 Republican presidential nomination. In response, a physician submitted, under the initials "K.G.," a tongue-in-cheek listing of the cabinet that would exist under MacFadden, including the newly created "Secretary of Aviation" for Lust. Lust was a popular figure by this time who conducted such a busy lecture schedule and practice, alternating between the "Yungborns" in Butler, New Jersey, and Tangerine, Florida, that he had become almost as well known as an airline traveler. Lust devoted a complete editorial in *Nature's Path* to a response.

Although Fishbein had *JAMA* as a personal editorial outlet, Lust had his own publications. Commencing with the *Naturopath and Herald of Health* in 1902 (which changed its name to *Herald of Health and Naturopath* in 1918), Lust continually published this and other monthly journals. In 1919 it became the official journal of the ANA, mailed to all members. Each edition contained the editorial column "Dr. Lust Speaking."

In the early 1920s, the "health fad" movement was reaching its peak in terms of public awareness and interest. As described, somewhat wistfully, in his June 1937 column, Lust announced the approach of the 41st Congress of Natural Healing under his guidance:

The progress of our movement could be observed in our wonderful congresses, in 1914 Butler, N.J., 1915 Atlantic City, 1916 in Chicago, 1917 Cleveland, 1918 New York, 1919 Philadelphia, 1920 and 1921 again New York, and 1922 in Washington, D.C., where we had the full support and backing of the Congress of the United States. President Harding received the president and the delegates of our convention and we were the guests of the City of Washington. Through the strenuous efforts of Dr. T.M. Schippel, Hon. Congresswoman Catherine Langley of Kentucky, and eight years of hard work financed and sustained by Dr. Schippel and her powerful friends in Congress, Naturopathy was fully legalized as a healing art in the District of Columbia and the definition was placed on record and the law affirmed and amended by another act which has been fully published over and over again in the official journal of the A.N.A., Naturopath.

In 1923 in Chicago, with the help and financing of the great and never-to-be forgotten Dr. Henry Lindlahr, we had a great convention. Not only were all the Naturopaths there but even to an extent our congress was recognized and acknowledged as official and of great importance by the medical people, particularly by the Health Commissioner of Chicago. We held a banquet, and there were discussions covering all platforms of the healing art. It was the first congress in the United States where medicine and Naturopathy in all its branches such as the general old-time Nature Cure, Hydrotherapy and Diet, Osteopathy, Naprapathy, Chiropractic, Neuropathy and Physiotherapy were represented on the same platform. The speakers represented every modern school of healing and the movement at that time was in the direction of an entirely recognized and independent school of healing. There were two camps, official medicine and official Naturopathy, the medical camp having all that is good and bad in medicine and surgery and all the other schools of healing that had sold their birthright and trusted to the allurement of organized medicine, such as Homeopaths, Eclectics, Physio-medics, and the Osteopaths to a large extent. The Osteopaths were always in the wrong camp when they went on mixed boards and Dr. Andrew Taylor Still, the father of Osteopathy, told me in 1915 that by compromising with medicine Osteopathy is doomed as the school that could have incorporated all of the natural and biological healing arts.

The year following we had the great congress in Los Angeles which has never been duplicated. We had to meet in two hotels because the crowds ran over 10,000. The glorious banquet will never be forgotten and the congress celebrated and demonstrated that the initial and first intent of the A.N.A. to teach the public Natural Living and Nature Cure was realized. We will never forget the glorious week in Los Angeles where the authorities and the whole city joined us. The success of that congress was largely due to the talent of Dr. Fred Hirsch, the successor to Prof. Arnold Ehret and the noble and generous Naturopaths of the A.N.A. of Cal. There was never a second congress like that.

Then we had the great congresses of New York in 1925, Indianapolis 1926, Philadelphia 1927, Minneapolis 1928, Portland, Oregon 1929, New York 1930, Milwaukee 1931, Washington, D.C., 1932, Chicago 1933, Denver 1934, San Diego 1935, and Omaha 1936.

In 1925 Lust began to try to reach more of the general populace through the lay publication *Nature's Path*. *The Naturopath* and *Nature's Path* were later merged because the self-supporting advertising and subscription monies were more available by publication to the general populace than to the members of the association (*The Naturopath*, 1902–1927; *Nature's Path*, 1925–1927; merged 1927–1933; separated 1934–1938; *Nature's Path*, 1939–1945).

How large a professional movement Lust inspired during this period of naturopathy's emergence was difficult to gauge. An extensive government survey was not undertaken until 1965. However, as Whorton described in *Nature Cures*,[21] naturopathy had an impact:

Those were messages that had enough appeal, evidently, to allow naturopathy to expand steadily through the first decades of the century until by 1923 Lust could estimate that there were nine thousand naturopaths, a "vast army of professional men and women" working on all continents to "rejuvenate and regenerate the world." His figures were undoubtedly inflated. An independent study [the work of the CCMC discussed later] put the number of naturopaths at "possibly 1500," allowing that if the "allied groups" that advocated drugless healing under other names [physiotherapy, sanipractic] were added on the total may reach 2500. Yet whatever their numbers, naturopaths had grown into a force not to be ignored.

Although Lust's claim of 9000 naturopaths worldwide is impossible to assess, 5000 practitioners may be a reasonable estimate of the reach of his naturopathy in the United States by the late 1920s and into the 1930s. As Whorton[21] reported, the mixer orientation within chiropractic was also becoming a growing presence. This orientation was a philosophy that tended to merge chiropractic and naturopathy in education and practice.[22] Although homeopathy has undergone a small revival in recent years, very few MDs now practice it. It is currently mainly of interest to naturopaths, who earn doctor of naturopathy (ND) degrees and to a few

chiropractors. Naturopaths closely resemble chiropractors in that they use spinal manipulative therapy and because so-called mixer chiropractors also use naturopathic methods such as heat, cold, hydrotherapy, physiotherapy, dietary supplements, and even some herbal and homeopathic remedies, which is why the traditional, or "straight," chiropractors disparagingly call them "medipractors." Until the middle of the twentieth century, a few mixer schools offered both DC and ND degrees, either as alternatives or together after an additional semester of study. Whorton noted a "1930 survey in which some 1,800 chiropractors participated, found, for example, that 1,124 employed hydrotherapy, 1,173 used light therapy, 1,257 provided electrotherapy, and a full 1,352 trusted vibration therapy."[21]

In January 1934, Lust commenced republication of the title *Naturopath and Herald of Health* in addition to *Nature's Path*. Each volume opened with his personal column, different for each publication. Both publications were issued through 1938, when the *Nature's Path* again became the sole publication until Lust's death in 1945.

After the *Universal Directory*, Lust continued to write volumes on naturopathic principles, although he was more of a synthesizer, organizer, lecturer, and essayist than a scientific documenter of naturopathic principles. His most enduring contributions may remain his early translations of Kuhne's and Just's works.

During the 1920s and up until 1937, Lust's brand of "quackery," so labeled by Fishbein, was in its most popular phase. Although the institutional markings of the orthodox school had gained ascendancy, before 1937 it had no real therapeutic success in the treatment of disease outside of the broad advancements in public health.

Lust's naturopathy, together with chiropractic and osteopathy, continued to be on the outside looking in, this lack of therapeutic advancement notwithstanding. Practitioners of all three movements were continually prosecuted for practicing medicine without a license, although they often won their cases by establishing to juries that their practices were (even according to the testimony of medical men) not the same as medicine at all. At the time orthodox practitioners could offer little or no expectation of cure for many diseases, and the "health food and natural health" movement was generally popular.

During the 1920s, Gaylord Hauser, later to become the health food guru of the Hollywood set, came to Lust as a seriously ill young man. Lust, through application of the nature cure, removed Hauser's afflictions and was rewarded by Hauser's lifelong devotion. His regular columns in *Nature's Path* became widely read among the Hollywood set.

As noted in *Other Healers, Other Cures*[15]:

> *The last big name in Naturopathy was Gaylord Hauser, a Viennese-Born food scientist (as one of his early books identified him) turned to Naturopathy in his later years. He is best remembered for advising the eating of living foods, not dead foods, and for escorting Greta Garbo around. In addition to fresh fruits and vegetables, Hauser's "Wonder Foods" were skinned milk, brewers yeast, wheat germ, yogurt, and black strap molasses.*

The naturopathic journals of the 1920s and 1930s are instructive. Much of the dietary advice focused on poor eating habits, including the lack of fiber in the diet and an overreliance upon red meat as a protein source. More than half a century later in the 1980s, the pronouncements of the orthodox profession, the National Institute of Health, and the National Cancer Institute finally accepted the validity of these early assertions by naturopaths that poor dietary and living habits (particularly smoking) would lead to degenerative diseases, including cancers associated with the lungs, the digestive tract, and the colon.

The December 1928 volume of *Nature's Path* was the first American publication of the works of Herman J. DeWolff, a Dutch epidemiologist who was one of the first individuals to assert, based on studies of the incidence of cancer in the Netherlands, that there was a correlation between exposure to petrochemicals and various types of cancers. He saw a connection between chemical fertilizers and their usage in some soils (principally clay) that led to poisons remaining in vegetables after they had arrived at the market and were purchased for consumption. Again, it was 50 years before orthodox medicine began to accept the wisdom of such concerns.

As Whorton noted in *Nature Cures*, naturopaths were less successful than osteopaths and chiropractors in accomplishing professionalization by the elevation of professional standards, including professional education. This occurred despite the formation of a National Board of Naturopathic Examiners of the ANA in 1940. There was constant internal bickering, which "by the 1940s had taken on a more ominous tone." Although "standards at naturopathic schools were steadily raised from the 1940s on, thanks to both professional idealism and the requirements of state licensing laws," based on "a perusal of the statutes of the dozen states in which naturopaths were licensed in the late 1940s," the divisive trends within naturopathy "would not begin to be reversed until the 1970s."

Whorton[21] observed that there was no misunderstanding where Lust himself stood on the need for professional standards:

> *Obtaining their own licensing statutes was perceived by alternative practitioners as a critical measure for purging incompetence and quackery from their own rank. "Where there is no official recognition and regulation," the founder of naturopathy, Benedict Lust maintained, "you will find the plotters, the thieves, the charlatans … (The) riff-raff opportunists bring the whole art into disrepute." By the time Lust said this, shortly before his death in 1945, frustrating experience had demonstrated that "that is the fate of any science—any profession—which the unjust laws have placed beyond the pale." In following the evolution of alternative medicine over the first third of the twentieth century, it is essential to keep in mind that constant battle of each system to bring itself within the pale.*

The Emerging Dominance of American Medical Association Medicine

In 1937, the status of conventional (allopathic) medicine began to change. The change came with the beginning of the era of "miracle medicine." Lewis Thomas in his interesting work *The Youngest Science*[23] compared his education and internship as a physician to his father's life as a physician. His father believed that bedside manner was more important than any actual medication offered by the physician. His father went into general surgery so that he could offer some service to his patients that actually made some change in their condition. Thomas pointed out that the major growth of "scientific medicine" until 1937 advanced diagnosis rather than offering any hope of cure.

This introduction of "miracle medicine," the social impact of World War II on health care, and the death of Lust in 1945 all combined to contribute a precipitous decline for naturopathy and natural healing in the United States. (During the war, the necessity for crisis surgical intervention techniques for battlefront conditions encouraged use of morphine, sulfa drugs, and penicillin for diseases not previously encountered in civilian life by American

combat soldiers. This resulted in rapid development of higher-technology approaches to medicine and highly visible successes.)

Lust recognized this and his editorializing became, if anything, even more strident. From the introduction of sulfa drugs in 1937 to the Salk vaccine's release in 1955, the American public became used to annual developments of miracle vaccines and antibiotics.

Lust died in September 1945 at the Yungborn facility in Butler, New Jersey, preparing to attend the 49th Annual Congress of his American ANA. In August 1945, for the official program of that congress held in October 1945 just after his death, he dictated the following remarks:

> *What is the present condition of Naturopathy? What is its future? I can give my opinion in a very few words. For fifty years I have been in the thick of the fight to bring to the American people the Nature Cure. During that period I have had an opportunity to judge what Naturopathy has done, and can accomplish and the type of men and women, past and present, who make up the Naturopathic ranks.*
>
> *Let us take the present situation first. What is Naturopathy accomplishing? The answer to that is: "Everything." Naturopathy holds the key for the prevention, alleviation and cure of every ailment, to man and beast alike. It has never failed in the hands of a competent Naturopath. Whatever the body can "catch"—that same body, with proper handling, can eliminate. And that takes in cancer, tumors, arthritis, cataract and the whole gamut of "incurable medical" disease and ailments. During my years of practice I, personally, have seen every type of human ailment and so-called serious "disease" give way to the simple, proven Naturopathic methods. I make no exception to that statement.*
>
> *Now let us see the type of men and women who are the Naturopaths of today. Many of them are fine, upstanding individuals, believing fully in the effectiveness of their chosen profession—willing to give their all for the sake of alleviating human suffering and ready to fight for their rights to the last ditch. More power to them! But there are others who claim to be Naturopaths who are woeful misfits. Yes, and there are outright fakers and cheats masking as Naturopaths. That is the fate of any science—any profession—which the unjust laws have placed beyond the pale. Where there is no official recognition and regulation, you will find the plotters, the thieves, the charlatans operating on the same basis as the conscientious practitioners. And these riff-raff opportunists bring the whole art into disrepute. Frankly such conditions cannot be remedied until suitable safeguards are erected by law, or by the profession itself, around the practice of Naturopathy. That will come in time.*
>
> *Now let us look at the future. What do we see? The gradual recognition of this true healing art—not only because of the efforts of the present conscientious practitioners but because of the bungling, asinine mistakes of orthodox medicine—Naturopathy's greatest enemy. The fiasco of the sulpha drugs as emphasized disastrously in our armed forces is just one straw in the wind. The murderous Schick test—that deadly "prevention" of diphtheria—is another. All these medical crimes are steadily piling up. They are slowly, but inevitably, creating a public distrust in all things medical. This increasing lack of confidence in the infallibility of Modern Medicine will eventually make itself felt to such an extent that the man on the street will turn upon these self-constituted oppressors and not only demand but force a change. I may not be here to witness this revolution but I believe with all my soul that it is coming. Yes, the future of Naturopathy is indeed bright. It merely requires that each and every true Naturopath carry on—carry on—to the best of his and her abilities. May God bless you all.*

The effects of postwar events on osteopathy and chiropractic were completely different from the effect on naturopathy. In the early days of osteopathy, there was a significant split between the strict drugless system advocated by A.T. Still (osteopathy's originator) and the beliefs of many MDs who converted to osteopathy because of its therapeutic value. The latter group did not want to abandon all of the techniques they had previously learned and all of the drugs they had previously used when those therapy techniques were sometimes effective. Ultimately, most schools of osteopathy, commencing with the school based in Los Angeles, converted to more of an imitation of modern orthodox medicine. These developments led to more of an accommodation between the California osteopaths and the members of the California Medical Association. (This developing cooperation between the California Osteopathic and Medical Association was one of the major issues leading to the downfall, in 1949, of Fishbein's editorial voice in *JAMA*.) Thus, osteopathy found a place in professional medicine, at the cost of its drugless healing roots and therapies.[9]

Naturopathy had become an element of chiropractic education and practice at least as early as 1910 with the founding of the Peerless College of Chiropractic and Naturopathy in Portland, Oregon.[22] From this point on, naturopathic education developed in two tracks: schools of naturopathy owned and operated by naturopaths and chiropractic schools that had naturopathic curricula in addition to the core chiropractic programs. These latter schools were a central part of the mixer orientation within chiropractic.[22,24]

Initial assessments of schools of naturopathy occurred in the 1920s and 1930s. These assessments came from those within, or allied with, allopathy and were therefore hardly unbiased, but much of the information in these assessments seemed credible. The progression of education in naturopathy would be expected to have been similar to that of chiropractic, if somewhat smaller in scale. In this regard, Wardwell noted[22]:

> *Wiese and Ferguson[25] identified 392 different chiropractic schools as having existed in the United States. When those for which there is no evidence of more than a year of operation are eliminated, the number is reduced to 188. Most of them probably produced few graduates—the number of schools increased rapidly to their largest between 1910 and 1926, and then contracted, particularly during the depression of the 1930s and World War II.*

The history of schools of naturopathy followed much the same pattern. Whorton[21] noted in *Nature Cures* that this was the case. The operators of these schools seemed, at least on the surface, aware of the kind of criticisms to which proprietary trade and professional schools were subjected: limited facilities, limited resources, and an emphasis on collecting revenue versus providing a full professional education.[22,24] The leading operators of schools of naturopathy sought, at least on paper, to respond to these criticisms. By letter agreement dated October 7, 1922, four of the most identifiable leaders of naturopathy—Benedict Lust, Joe Shelby Riley, F.W. Collins, and Henry Lindlahr—committed to the formation of the Associated Naturopathic Schools and Colleges of America and committed themselves as "the Presidents of Naturopathic Schools in the United States of America" to specific educational minimums "on and after January 2, 1923": "all

matriculants must have a primary school education* and all naturopath courses must be composed of four years of six months each." Additionally, the letter provided that "time allowance or credits may be given to practitioners in the field who desire to take up the naturopathic courses, and to licensed physicians of other methods of healing," the amount of such credit being left to each school's discretion.

In the summer and fall of 1927, representatives of the AMA's Council on Medical Education and Hospitals conducted inspections—unannounced and incognito—of schools of "chiropody, chiropractic, naturopathy, optometry, osteopathy, physical therapy, as well as a large number of institutions." From these inspections, several reports were generated, including the Council's report on "Schools of Chiropractic and Naturopathy in the United States," which appeared first as part of the Council's *Annual Report, 1928*, and later as reprinted in *JAMA.* The report identified 40 schools of chiropractic and 10 schools of naturopathy and detailed the inspections of "some schools of Chiropractic and of Naturopathy": Palmer School of Chiropractic (a straight school), National College of Chiropractic (a mixer school that was reported as having recently purchased and assimilated Lindlahr College of Natural Therapeutics), Los Angeles College of Chiropractic (another leading mixer school), the combined American School of Naturopathy, Inc. and American School of Chiropractic, Inc. (Lust's own New York City schools, although Lust was observed to have been "in Florida" at the time of the inspections), and the Naturopathic College and Hospital of Philadelphia. The reports were predictably negative with regard to facilities, resources, and the clearly proprietary nature of the establishments.

Louis Reed of the Committee on the Costs of Medical Care, in discussing "Naturopathic Schools"[24] relied heavily on this report from the AMA's Council and observed that "in 1927, according to the American Medical Association, there existed twelve naturopathic colleges with not over 200 students. These figures would probably hold good for the present time." Reed also concluded that there were "a considerable number of miscellaneous drugless healers of a type similar to chiropractors practice in this country" as of 1932 and that "the naturopaths form the largest group of these practitioners.… Of these various cults, only the naturopaths and the sanipractors have any considerable membership. Many of the (other) cults are really part of the naturopathic group."[24]

As to numbers of drugless practitioners, Reed observed that "only the roughest estimate can be made—probably there are about 2500," of which naturopaths "number possibly 1500," and sanipractors—"only the name distinguishes sanipractors from the naturopaths"—numbered some 500 in their Washington state "stronghold." Reed also observed that as of 1932: "A few states—Connecticut, Florida, Oregon, South Carolina, Utah, Washington and the District of Columbia—provide for licensing of naturopaths as limited practitioners.… In addition to those mentioned, certain states (Alabama, Colorado, Illinois, Indiana, Michigan, Ohio, Pennsylvania, New Jersey, and Wyoming) make (other) provision for the licensing of drugless or limited practitioners."[24]

Reed's work for the CCMC, although clearly biased against all of the healing philosophies he identified as "medical cults" (a la Fishbein), principally osteopathy, chiropractic, and naturopathy, was the only work that attempted to survey the presence and impact of these schools of healing in the United States in the 1920s and 1930s.* A decade later, in April 1945, another work of this kind appeared in the *Rhode Island Medical Journal*. The article, "Naturopathic Legislation and Education," was written by the Rhode Island Medical Society's Executive Secretary, John E. Farrell, to set out some of the society's reasons for opposing legislation that would license naturopathy in Rhode Island. The article noted that according to the 1942–1943 Report of the Committee on Education of the ANA, 13 schools of naturopathy in the United States met the criteria of the ANA; the article went on to make a lengthy "Report on Schools" through visits to most of the identified schools.† The predictable criticisms of these schools as underfinanced, underresourced, and proprietary in nature appeared once again, although by actual detail of description, National College (Chicago) and Western States (Portland) seemed to be well-established, functioning mixer schools of chiropractic and naturopathy.

The effect on chiropractic of the post World War II years was somewhat different. Because of educational recognition under the G.I. Bill, the number of chiropractors in the country grew substantially, and their impact on the populace grew accordingly. The sect eventually grew powerful enough in terms of numbers and economic clout that it could pose a legal challenge to the orthodox monopoly of the AMA. However, in the immediate postwar years, the AMA gained tremendous political clout. Combined with the American Legion and the National Board of Realtors,[26] these three groups posed a powerful political triumvirate before the U.S. Congress.

These years, called the years of the "great fear" in Caute's book by that name,[27] were the years during which to be unorthodox was to be "un-American."

Across the country, courts began to take the view that naturopaths were not truly doctors, since they espoused doctrines from "the dark ages of medicine" (something American medicine had apparently come out of in 1937) and that drugless healers were intended by law to operate without "drugs" (which became defined as anything a person would ingest or apply externally for any remedial medical purpose). In this regard, the Washington State Supreme Court case of *Kelly v. Carroll*‡ and the Arizona State Supreme Court case of *Kuts-Cheraux v. Wilson* document how significant limitations were placed on naturopaths under the guise of calling them "drugless healers."

In the state of Tennessee, as a reaction to the 1939 publication of the book *Back to Eden* by herbalist Jethro Kloss, court action initiated by the Tennessee State Medical Association led first to the publishers being forbidden to advertise the book for any therapeutic purpose. They were allowed only to acknowledge that it was in stock. Then, following a serious licensing scandal during

*"Primary education"—circa 1922—was an eighth-grade education, and this educational base would have been the same as that required by chiropractic.

*The results of Reed's work are also summarized in the CCMC's Publication No. 27, The Costs of Medical Care, Falk, Rorem and Ring (1933), p. 292, as 'Naturopaths and Other Drugless Healers.'

†With lengthy discussion of Central States College of Physiatrics (Eaton, Ohio), The Colorado Mineral Health School (Denver), Columbia College of Naturopathy (Kansas City), First National University of Naturopathy (Newark, New Jersey, earlier the United States School), The Metropolitan College (Cleveland), The Nashville College of Drugless Therapy (Tennessee), The National College of Drugless Physicians (part of the National College of Chiropractic, Chicago), The Polytechnic College and Clinic of Natural Therapeutics (Fort Wayne, Indiana), The Southern University of Naturopathy and Physio-Medicine (Miami), The University of Natural Healing Arts (Denver), and The Western States College (Portland, Oregon).

‡The defendant was Otis G. Carroll of Spokane, Washington. He and his brother, Robert V. Carroll, Sr., of Seattle were longtime associates of Benedict Lust. As members of Lust's American Naturopathic Association, they had advanced naturopathy's presence in Washington state through the Washington State Naturopathic Association.

the war years, the Tennessee State Legislature declared the practice of naturopathy in the state of Tennessee to be a gross misdemeanor, punishable by up to one year in jail.

Although it was under considerable public pressure in those years, the ANA undertook some of its most scholarly work, coordinating all the systems of naturopathy under commission. This resulted in the publication of a basic textbook on naturopathy (*Basic Naturopathy* published in 1948 by the ANA[28]) and a significant work compiling all the known theories of botanical medicine (as commissioned by the ANA's successor after its 1950 name change to the American Naturopathic Physicians and Surgeons Association), the *Naturae Medicina* published in 1953.[29] Naturopathic medicine began splintering when Lust's ANA was succeeded by six different organizations in the mid-1950s.

The primary organizations among these were the successor to the ANA, which underwent a name change in 1950 to the American Naturopathic Physician and Surgeon's Association, and subsequently changed to the American Association of Naturopathic Physicians (AANP) in 1956, and the International Society of Naturopathic Physicians formed under the leadership of M.T. Campenella of Florida shortly after Lust's death, with its American offshoot, the National Association of Naturopathic Physicians.

In the face of the AMA's determination to eliminate chiropractic, and with it naturopathy—healing philosophies that were linked through the mixer orientation within chiropractic (during the 1930s and through the 1960s the majority camp within a divided chiropractic)—naturopathy went through a period of decline described by Hans Baer (see Bibliography).

Walter Wardwell was a sociology professor who became an early leader in what developed as a subspecialty in the 1950s: medical sociology. His earliest work, starting with his doctoral dissertation (1951) at Harvard, focused on chiropractic as an example of a marginalized health profession (see Bibliography). As early as his doctoral dissertation, Wardwell discussed naturopathy as an adjunct discipline to chiropractic in the context of the continuing division of chiropractic into mixers and straights. As he later noted[30]:

> *Comparison of the survival of chiropractic with that of osteopathy and naturopathy is a quite different matter which does not involve metaphysical or epistemological differences between them. Furthermore, the overlap in theory between chiropractic, osteopathy and naturopathy is very great. Differences between osteopathic and chiropractic manipulative treatment appear to be more a matter of who applies the technique rather than differences in technique itself. The distinction between chiropractors and naturopaths is even more blurred because they often trained at the same schools and sometimes they studied both fields simultaneously. As recently as 1948, three of the currently accredited chiropractic colleges offered N.D. (Doctor of Naturopathy) and D.C. (Doctor of Chiropractic) degrees.*

In this context he described naturopathy as a school of healing that became extinct as two historical factors converged: the death of Lust in 1945, leaving naturopathy without its "founder," and the mandate in the early 1950s by the major mixers' professional group, the National Chiropractic Association (NCA), that it would no longer accredit chiropractic schools that granted degrees in naturopathy:

> *In the case of naturopathy, chiropractic's victory is nearly complete. Although there may still be up to 2000 naturopaths in practice* with naturopaths licensed in a few states, and one small school in Portland, Oregon, still offers naturopathic degrees, none of the schools that formerly offered both chiropractic and naturopathic degrees currently does so. With practically no new recruits entering the profession, naturopathy must disappear.*

By the late 1970s, Wardwell had learned of efforts in the Pacific Northwest to keep naturopathy alive. In his chapter in the *Handbook of Medical Sociology*, Wardwell noted this presence in the Northwest (which had received no mention in the first two editions in 1963 and 1972)[31]:

> *The accrediting of chiropractic colleges is encouraging uniformity, not only in curricula but in scope of practice. Those colleges that formerly offered the Doctor of Naturopathy (N.D.) as well as the D.C. degree have ceased doing so, leaving naturopathy with only one remaining small college in Portland, Oregon.*

By publication of his masterwork, *Chiropractic: History and Evolution of a New Profession* (1992),[22] Wardwell devoted substantial attention to the impact of naturopathy on the mixer orientation within chiropractic and traced naturopathy's final educational decline to the untimely death in 1954 of William A. Budden, DC, ND, the president of Western States Chiropractic College (WSCC; Portland, Oregon). After Budden's death, WSCC continued to teach naturopathy until 1958, but dropped its ND degree program in 1956. This was the last resistance to the position of the accrediting committee of the NCA, and no chiropractic ND programs remained. Wardwell observed, though, that the seeds of a naturopathic reemergence had been planted in the Northwest after Budden's death and that naturopathy might survive.

The last ND diplomas were granted at WSCC in 1958 to students who were enrolled in the ND program at the time of Budden's death. Brinker[32] noted the following:

> *Political pressure from the chiropractic profession had begun in the late 1940s to force chiropractic schools to relinquish programs granting naturopathic degrees. After threatening loss of accreditation, the National Chiropractic Association finally forced Western States College to drop its School of Naturopathy in 1956, and it became exclusively Western States Chiropractic College.*

Efforts to keep naturopathy alive through education and licensure were examined by two reports prepared in 1958, a time when the Utah legislature was reexamining naturopathy's licensure in the aftermath of a case from the Utah Supreme Court that had dealt its practicing NDs a crippling blow. The first was *A Study of the Healing Arts with a Particular Emphasis Upon Naturopathy* (November 1958), prepared as "A Report to the Utah Legislative Council" by legislative council staff. As part of its work, the staff conducted inquiries of and site visits to seven schools accredited by the Utah Naturopathy Examining Board as of August 1957.

Separately, the Bureau of Economic and Business Research* of the University of Utah (BEBR) undertook a study focusing on schools that had granted naturopathy degrees and produced *Survey of Naturopathic Schools* ("Prepared for the Utah State Medical Society," December 1958). Preparation of the study was, as noted in the title, undertaken by the university research program at the request of the state medical society, but the preparation of the study was independent, and "no attempt was made by that group to influence the results of the study" (Foreword and Acknowledgements).

*As to those calling themselves naturopaths, this number was considerably too high, as will become apparent.

*Now the National Bureau of Economic Research.

The BEBR study, done with the requested cooperation of investigators from five other universities located in various sections of the United States, surveyed all of the schools listed by Utah licensees as schools of graduation or schools attended, using records maintained by the Utah Department of Business Registration.[10] Because the state of naturopathic education in the 1950s is relevant, some observations from this study are worth noting[33]:

> *One of the most important results to emerge from this study is that there are virtually no schools now teaching naturopathy.*

Of the twenty-six schools investigated during this study, only nine were still in existence in the fall of 1958. Of these nine, only three are now granting naturopathic degrees and two others are teaching naturopathy.

Of the three schools granting ND degrees, the study found that one school, Sierra States University in California, began offering a "postgraduate" ND degree after the most highly respected chiropractic program in the country, Los Angeles College of Chiropractic, had discontinued its ND degree program in 1948. National College of Naturopathic Medicine (NCNM), the Oregon school, had—in 1957, its first year of operation—four ND students who were starting at NCNM and 60 enrolled "postgraduate" DCs pursuing ND degrees. The school had been recognized by the Utah examining board but had not yet granted degrees. The third school granting ND degrees as of 1957-1958 was the Central States College of Physiatrics in Eaton, OH, essentially the one-man operation of H. Riley Spitler, author of *Basic Naturopathy* (published by the ANA in 1948). This school granted a Doctor of Mechanotherapy (DM) degree, recognized in only Ohio and Alabama by law, or an ND degree to anyone who sought licensure in a state where an ND degree would qualify a graduate for licensure. The course of study for both degrees was the same, and the school had graduated 10 students in the previous 2 years. Its ND degrees were recognized in Utah.

By 1955, the AANP, as it ultimately became known, had recognized only two schools of naturopathic medicine, the Central States College of Physiatrics in Eaton, Ohio, under the leadership of H. Riley Spitler, and Western States College of Chiropractic and Naturopathy located outside Portland, Oregon, under the leadership of R.A. Budden. Budden was a Lindlahr graduate and among the group that took over control of the Lindlahr College after Lindlahr's death in the 1920s. He moved west after World War II when the northwestern states, including Oregon, became the last bastion of naturopathic medicine in this country.

This state of affairs was accurately described by Homola[34] in his book on the history and evolution of chiropractic:

> *As of 1958, only five states (Arizona, Connecticut, Oregon, Virginia and Utah) separately classified and provided licensing provisions for the naturopath. A few states, however, did permit licensing of drugless healers following examination by (a) board. (A good number of states have repealed their laws licensing naturopaths in recent years.) Chiropractic schools that employ the use of physiotherapy teach a course that is very similar to the practice of naturopathy. Likewise, the three or four naturopathic schools still operating today have a curriculum similar to that of many chiropractic colleges. In fact, at least four chiropractic colleges awarded naturopathic degrees along with the chiropractic degree before they came under the jurisdiction of the national Chiropractic Association. With the approval of this organization, the schools were prohibited from issuing naturopathic degrees. This practically amounted to a death-dealing blow to the profession of naturopathy.*[34]

In 1967, the U.S. Department of Health, Education, and Welfare; the Public Health Service; and the National Center for Health Statistics (NCHS) published Public Health Service Publication number 1758, *State Licensing of Health Occupations*. With the assistance of The Council of State Governments, the NCHS collected data regarding licensure of health professionals at the state level. "Chapter 8: Naturopaths" recorded the available data for the naturopathic profession as of the mid-1960s. In summary, the NCHS identified five states and the District of Columbia as licensing naturopaths as of 1967: Arizona, Connecticut, Hawaii, Oregon, and Utah. California and Florida were identified as renewing existing licenses but granting no new licenses. The publication reported that by 1965, California had renewed 66 licenses and Florida, 136. Licenses in effect by state were: Arizona (100), Connecticut (47), Hawaii (14), Oregon (148), and Utah (42). No numbers were provided for the District of Columbia. The report stated the following[35]:

> *In addition to Doctors of Naturopathy (ND) there are other limited branches of medicine; these have not been included in the study. In the State of Washington the Drugless Therapeutics Examining Committee functions (for such licensure). The Ohio law states which branches are to be specified on certificates issued by the State Medical Board to limited practitioners. No attempt has been made to collect information on these drugless healers who are few in number.*

Active state practitioners were also numbered (although the reason for the differentiation is not clear) as: Arizona (53), Connecticut (29), Hawaii (13), and Oregon (121). Given the existence of approximately 50 practitioners at the time in Washington, and some practicing in Idaho under a decision of the Idaho Supreme Court, there appear to have been perhaps as many as 600 to 700 remaining naturopaths practicing at the end of the 1960s.*

According to documentation provided to the federal Department of Health Education and Welfare in 1968 by the again-remaining professional association—the National Association of Naturopathic Physicians—only 17 degrees were granted from 1960 to 1968. By 1968, this association had 168 members and estimated that there were perhaps 500 "active" naturopaths in the United States. Congress adopted Medicare in 1965. The legislation covered payment for the services of physicians (essentially MDs and DOs), hospital services, and "other therapeutic services" that would commonly be provided through these conventional means. As Wardwell reported,[22] in 1967, Congress directed the Secretary of the Department of Health, Education, and Welfare (HEW), Wilbur Cohen, to study the inclusion services of "additional types of licensed practitioners." The surgeon general and other HEW staff prepared the resulting *Independent Practitioners under Medicare* using advisory committees only (Wardwell served on the Expert Review Committee for Chiropractic and Naturopathy), which actually had little input. This report documented the ebb tide of naturopathy's "period of decline"

*The State Licensing of Health Occupations; U.S. Department of Health, Education, and Welfare; and the National Center for Health Statistics Public Health Service Publication No. 1758 (1967) reported: "Naturopaths are specifically licensed in at least five States and the District of Columbia. The absence of a State from this list does not imply that there are no licensed naturopaths. Illinois, for example, could be covered by the medical practice act. Texas and Virginia provide for naturopaths on examining boards but no information is available on licensing practices. Elsewhere licensing powers have been abolished and no new licenses have been issued; for example, in 1965 naturopathic licenses renewed in California numbered 66 and in Florida, 136."

as Baer later labeled it.[36] The section of the report *Naturopathy* concluded that as of 1968:

> *Naturopathic theory and practice are not based on the body of basic knowledge related to health, disease, and health care which has been widely accepted by the scientific community. Moreover, irrespective of its theory, the scope and quality of naturopathic education do not prepare the practitioner to make an adequate diagnosis and provide adequate treatment.*

Considering the state of the profession in 1968, these negative assessments were hardly unexpected.

THE MODERN REJUVENATION

After the counter culture years of the late 1960s and feeding of an American disenchantment with organized medicine which began after the miracle drug era faded, exposing some of orthodox medicine's limitations, alternative medicine began to gain new respect. Naturopathic medicine underwent an era of rejuvenation as a late 1970s consumer interest in more "holistic" medicine began to emerge.

As succinctly described in Cassedy's[37] *Medicine in America: A Short History*, this phenomenon, which was not limited to naturopathic medicine, was consistent with the modern and continuing, "search for health beyond orthodox medicine":

> *It should not have been surprising to anyone that certain organized therapeutic sects continue to exist in mid–twentieth century America as successful and conspicuous alternatives to regular medicine. This is not to say that they offer the same threats to the medical establishment or play the same roles as their nineteenth-century counterparts had, as complete therapeutic systems. But they do continue to hold a strong collective appeal for individuals who mistrust or are somehow disenchanted with mainline medicine. They have appealed also to antiauthoritarian sentiments that flourish throughout society. Moreover, as earlier, they satisfy various needs that regular medicine continues to neglect or ignore.*

The same author, in describing the post-World War II decades and the changing fortunes of such healing theories as naturopathic medicine, observed as follows:

> *The period also brought about the renewal or updating of certain previously widely used therapies and considerable experimentation with others, some of them exotic. To an extent this trend represented the rediscovery by trained physicians, nurses, and other regular health professionals of certain values and older styles of therapy. The participation of such professionals proved to be an essential ingredient in the rebirth of several such therapies. However, the major reason for the new successes was the wide-spread active interest and involvement of America's literate lay people in the search for more personal or humane forms of treatment.*

As another author, John Duffy,[38] observed in *From Humors to Medical Science*:

> *Since health is too closely related to cultural, social, and economic factors to be left exclusively to doctors, American lay people have always engaged in do-it-yourself medicine, resorted to "irregulars and quacks," and supported health movements. As a result of the current fad for physical fitness, our streets are beset by sweat-suited individuals of all ages doggedly jogging their way to health and long life. In addition, stores selling "natural" foods are flourishing, physical fitness salons have become a major business, and anti-smoking and weight-loss clinics and workshops are attracting thousands of individuals bent on leading cleaner and leaner lives. And those for whom physical activity in itself is not enough are seeking physical and mental well-being through faith healing, yoga, and a host of major and minor gurus.*

When neither mental effort nor physical exercise can solve medical problems, the sceptics of modern medicine can always turn to the irregulars. A recent estimate places a number of Americans who have relied on an irregular practitioner at some time in their lives at 60 million, and, aided by the high cost of orthodox medicine, irregular medical practice appears to be on the rise…

At the beginning of this period of rejuvenation, the profession's educational institutions had dwindled to one, the National College of Naturopathic Medicine (which had branches in Seattle, Washington and Portland, Oregon), which was founded after the death of R.A. Budden and the conversion of Western States College to a straight school of chiropractic. Kruger's[15] book *Other Healers, Other Cures* described it as follows in 1974:

> *Today, Naturopaths in seventeen states are licensed to diagnose, treat, and prescribe for any human disease through the use of air, light, heat, herbs, nutrition, electrotherapy, physiotherapy, manipulations, and minor surgery. At present, one can earn an D.N. [a misnomer, actually—N.D.] degree at the National College of Naturopathic Medicine in Seattle and Emporia, Kansas, [where, by contract, the first two years of the four-year medical education were then taught], or the new North American Naturopathic Institute in North Arlington, New Jersey [there is also a school in Montreal]. The four-year curriculum covers many standard medical courses—anatomy, bacteriology, urology, pathology, physiology, X-ray reading etc.—but also includes botanical medicine, hydrotherapy, electrotherapy, and manipulative technique…*

The public, by the late 1970s, was particularly ripe for another rejuvenation of naturopathy's brand of "alternative" health care. As described in Murphy's *Enter the Physician: The Transformation of Domestic Medicine*, 1760–1860, when discussing this cyclical rejuvenation in the mid-twentieth century[39]:

> *Contemporary crusaders still stress prevention as the layperson's primary duty, but a growing chorus is calling for every person to assume the newly proactive role in his or her own health care.*

What would this entail? There are probably as many answers to this question as there are respondents, but it is striking to note how many of the solutions would have been familiar to our ancestors who lived between 1760 and 1860. One recurring idea, for instance, is that each person knows his or her own constitution history the best, and therefore has a duty to communicate that knowledge to medical personnel. Another is a refurbished concept of *vis medicatrix naturae*, the belief that many diseases are self-limiting and therefore do not require much medical intervention—and certainly not the amount or the sort to which contemporary Americans are accustomed. Most significantly, today's analysts are calling on professionals and non-professionals to build and nurture a health care partnership very much like that envisioned by nineteenth-century health publicists: a partnership based on mutual respect, clear understanding and faithful execution. In that scenario, both as it originally evolved and in its updated version, it is the doctor who directs treatment, but crucial to a successful outcome are the informed and responsible actions of the patients, other care givers, and the patient's family and friends.

In 1978, the John Bastyr College of Naturopathic Medicine was formed in Seattle, Washington, by Joseph E. Pizzorno, Jr., ND (founding president), Lester E. Griffith, ND, and William Mitchell, ND (all graduates of the National College of Naturopathic Medicine), and Sheila Quinn, who felt that it was necessary to have more institutions devoted to naturopathic care and the teaching of naturopathic therapeutics. To differentiate Bastyr from the other "irregular"[38] schools, Pizzorno coined the term "science-based natural medicine" and developed the curriculum to implement it. Bastyr's co-founder and first president, Joseph Pizzorno, recognized that "anecdotal and unverified 'cures', particularly when associated with unusual therapies do our cause little good." Consequently, instruction at the school "has concentrated more on the scientifically verifiable aspects of natural medicine and less on the relatively anecdotal nature cure aspects."[21]

In *Other Healers, Unorthodox Medicine in America*,[40] a volume written to provide "a scholarly perspective on unorthodox movements and practices that have arisen in the United States" (from the editor's preface), author Martin Kauffman, a modern expert in homeopathy from the Department of History at Westfield State College, detailed Bastyr's homeopathic requirements to graduate:

> *In 1978, three naturopathic practitioners in Seattle founded the John Bastyr College of Naturopathic Medicine. During the sixth quarter all students at that school are required to take 44 hours of course work in homeopathy, after which they may elect another 66 hours and up to 238 hours of clinical homeopathic instruction. The significance of the naturopathic schools to the resurgence of homeopathy is demonstrated by the fact that "about one third of the graduating class specialized in homeopathic practice, a total of about 50 each year in all."*[40]

During the late 1970s, other naturopathic doctors also recognized the need to establish educational institutions for students of naturopathic medicine; subsequent efforts included colleges in Arizona (the Arizona College of Naturopathic Medicine), Oregon (the American College of Naturopathic Medicine), and California (the Pacific College of Naturopathic Medicine). Unfortunately, none of these three survived.

As public demand for natural healing grew in the 1980s and 1990s, the emerging profession continued to grow a breadth and quality of educational opportunity for those seeking accredited doctorate-level programs in naturopathic medicine.

With thriving enrollments at Bastyr and National College, the Council on Naturopathic Medicine was founded in 1978 to establish and oversee educational standards, and today is recognized by the U.S. Secretary of Education as the national accrediting agency for programs leading to the Doctor of Naturopathic Medicine (ND or NMD) or Doctor of Naturopathy (ND) degree. To further build on the cornerstone of accredited education and ensure educational quality, in 1986 the Naturopathic Physician Licensing Examination became the first national board exam for graduates; today, graduates must pass a two-part medical exam in biomedical and clinical sciences before they are eligible to use the title "ND." This exam is modeled after the conventional medical board exam for allopathic graduates, the U.S. Medical Licensing Exam, which assigns the "MD" license. This training was described in detail in a report from 2001 by the University of California San Francisco Center for Health Professions: "Naturopathic physicians are typically trained in a wide array of alternative therapies including herbology, homeopathy, massage, hydrotherapy, physical medicine, behavioral medicine, Traditional Chinese medicine, Ayurvedic medicine, acupuncture, and nutrition therapy, as well as clinical practices such as minor surgery, pharmacology and obstetrics."[41]

With educational standards set, throughout the 1990s and 2000s, a select group of new programs and institutions attained accreditation status with the Council on Naturopathic Medicine: Southwest College of Naturopathic Medicine and Health Sciences, Tempe, Arizona; the College of Naturopathic Medicine at the University of Bridgeport, Connecticut; the Canadian College of Naturopathic Medicine, Toronto, Ontario; and, in 2011, the Boucher Institute of Naturopathic Medicine, British Columbia, Canada. The establishment of multiple geographic locations for this type of education paves a solid future for the profession, providing hundreds of newly graduated naturopathic doctors every year in the United States and Canada.

There are favorable commentaries on the current state of naturopathic medicine. *Other Healers, Unorthodox Medicine in America*,[40] is a volume written to provide "a scholarly perspective on unorthodox movements and practices that have arisen in the United States." As described in the Encyclopedia of Alternative Health Care by Olsen[42]:

> *While naturopathic medicine is now legal (in several states), many naturopaths practicing in other states are old-timers, practicing under their original "drugless therapy" licenses, issued before laws prohibiting new naturopathic practices went into effect.*

In cooperation with regional associations, the AANP has won licensure and scope of practice protection at a steady rate on par with the growth of schools accredited by the Association of Accredited Naturopathic Medical Colleges. As of 2011, 15 U.S. states, the District of Columbia, five Canadian provinces, and the U.S. territories of Puerto Rico and the U.S. Virgin Islands regulate the naturopathic profession (Box 4-1).

Baer's interest in the evolution of chiropractic as a philosophy of healing led him to Wardwell's work and to Wardwell's earlier scholarship, which had been tied to the mixer orientation within chiropractic. Baer took note of his descriptions of naturopathy as a near-extinct philosophy. Predictions of extinction were consistent among the assessments of social scientists in the 1970s

BOX 4-1 States/Provinces that Regulate the Naturopathic Profession

United States
Alaska
Arizona
California
Connecticut
District of Columbia
Hawaii
Idaho
Kansas
Maine
Minnesota
Montana
New Hampshire
North Dakota
Oregon
Utah
Vermont
Washington
U.S. Virgin Islands
Puerto Rico

Canada
Alberta
British Columbia
Manitoba
Nova Scotia
Ontario
Saskatchewan

As of 2011, the following states have ND legislation pending:
Colorado
Illinois
Iowa
Massachusetts
New York
North Carolina
Pennsylvania
Wisconsin

and continued into the mid-1980s. Twaddle and Hessler, Rosengren, Whorton, and most notably Wardwell, all discussed naturopathy as a once-observable but marginalized philosophy of health and healing at odds with the conventional medical claims of a scientific medicine (see Bibliography). These social scientists placed naturopathy's demise sometime in the 1950s when chiropractic severed its open naturopathic link by terminating ND programs.

Baer, before Wardwell, took special note of Bastyr and the professionalization represented by its scientific medicine–based curriculum and the publication of a John Bastyr College of Naturopathic Medicine project, *The Textbook of Natural Medicine*.

In his 1992 *Medical Anthropology* article[36] "The Potential Rejuvenation of American Naturopathy as a Consequence of the Holistic Health Movement," Baer detailed his own view of Naturopathy's "three stages of development" noted at the outset of this chapter. Besides relying on material covered in the original chapter of "The History of Naturopathic Medicine," which first appeared in 1985, Baer covered much of the new material regarding the emerging (1900–1930s) and declining (1940–1970s) stages of naturopathy.

Baer particularly broke new ground with his recognition of a "potential rejuvenation" of naturopathy as naturopathic medicine and his recognition that the profession had knowingly or unknowingly adopted a recognized survival strategy as a matter of organizational policy: professionalization. Baer also advanced a theory regarding the "potential rejuvenation" as tied to the emergence in the 1970s of holistic medicine. Holistic medicine, as a philosophy of healing, had a cultural affinity with the eclecticism inherent in naturopathic philosophy. In his 2001 book,[43] *Biomedicine and Alternative Healing Systems in America*, Baer updated this view of the status of naturopathic medicine in a chapter entitled "Naturopathy and Acupuncture as Secondary Professionalized Heterodox Medical Systems." With the passage of the additional 10 years, Baer observed[43]:

> *Unlike chiropractic, which no longer poses a serious threat to biomedicine because of its status as a specialty emphasizing spinal manipulation, a rejuvenated naturopathy finds itself in direct competition with biomedicine because both systems claim to provide a comprehensive approach to health care.*
>
> *As osteopathy and chiropractic did earlier, naturopathy … (is) increasingly incorporating the theory and social organization of biomedicine.*
>
> *(N)aturopathy with (its) reductionist philosophy and (its) focus on individual responsibility for healthy living may well undergo further growth in an era of growing health costs.*

THE TWENTY-FIRST CENTURY AWAITS

Baer carried his examination of the sociopolitical aspects forward in his 2001 article,[44] "The Sociopolitical Status of U.S. Naturopathy at the Dawn of the 21st Century" which examined the state of naturopathic medicine as it prepared to enter the twenty-first century. Although "professionalized naturopathy has undergone tremendous growth and legitimization since the late 1970s, nevertheless, it finds itself in a tenuous situation at the dawn of the twenty-first century in that its strength is confined primarily to the Far West and New England; it faces increasing competition from the partially professionalized and lay naturopaths; and it faces the danger of being overshadowed by a powerful biomedical system that is increasingly incorporating aspects of holistic health into its own practice."

He offered no definitive answers to these questions of naturopathic medicine's future, but he also highlighted areas needing further attention by social scientists: continued exploration of the reasons for naturopathy's decline and rejuvenation and continued study of the naturopathic profession in recognition of its state of professionalization.

In closing, Baer observed: "In sum, while changes in the popular ideas about health and healing unleashed the social forces that enabled professional naturopathy to get back on its feet, those same social forces may overwhelm its core claim to being a unique, natural approach to healing."

Whorton expressed the view that in many respects the transition from the marginalized naturopathy to the professionalized naturopathic medicine has now been accomplished.[45] He traced his view of this transformation as part of the larger transformation "from alternative medicine to complementary medicine" on the part of osteopathy, chiropractic, and naturopathy. Whorton described the factors that allowed this transformation even after the death of Lust in 1945: the issue of the "field's lack of a scientific basis" was determined internally when the "died-in-the-wool believers in 'nature cure'" were outlasted by the "liberal practitioners belonging to the so-called western group, naturopaths concentrated in the western states who recognized the validity of mainstream medicine's scientific foundation and sought to incorporate biomedical science into their own system and apply it under the guidelines of naturopathic philosophy."

As Whorton noted, "a key figure among the pseudo-medicals was John Bastyr—a practitioner in Seattle since the 1930s, and particularly well-known for his advocacy of natural childbirth." Bastyr, Whorton noted, "recognized the necessity of naturopathy staying abreast of advances in biomedical science and applying those advances 'in ways consistent with naturopathic principles'."[21] Bastyr was directly involved with the formation and maintenance of the NCNM during the years of naturopathy's decline and lived to see much of "the short history of John Bastyr College (of Naturopathic Medicine) (which) is the most compelling illustration of the triumphant rebirth of naturopathy as naturopathic medicine."[21]

Bastyr has been called "The Father of Modern Naturopathic Medicine" by Pizzorno, ND,[45] the moving spirit behind the professionalization of naturopathic medicine and the founding president of Bastyr University. No individual has carried the practice of NDs in the United States in the way that Lust did, but Bastyr and the others profiled by Kirchfeld and Boyle in *Nature Doctors* kept naturopathy alive during its decline in the 1950s and 1960s so that it could, in time, reemerge.

The movement continues to grow, and so, the impact of natural healing has come full circle. In an era where the statistical number of persons born who are expected to contract cancer, now recognized as a degenerative disease, has increased rather than declined, and the incidence of other degenerative diseases (arthritis, arteriosclerosis, atherosclerosis, etc.) has increased in direct relation to the lengthening of life expectancies produced by improved sanitation and nutrition (although speciously claimed by AMA medicine to be the result of their therapies), the early teachings of Lust, Lindlahr, and others appear to have more validity than ever.

INTRODUCTION

This chapter examines the philosophical foundation of naturopathic medicine and its modern applications. Unlike most other health care systems, naturopathy is not identified by any particular therapy or modalities (e.g., conventional medicine, drugs and surgery; chiropractic, spinal manipulation). A wide variety of therapeutic styles and modalities are found within the naturopathic community (Box 5-1). For example, there are still practitioners who adhere to the strict "nature cure" tradition and focus only on diet, "detoxification," lifestyle modification, and hydrotherapy. There are also those who specialize in homeopathy, acupuncture, or natural childbirth. At the other end of the spectrum are naturopathic physicians who use botanical medicines, nutraceuticals, and pharmacology extensively to manipulate the body's biochemistry and physiology. Finally, there is the majority, who practice an eclectic naturopathic practice that includes a little of everything.

Since its inception 120 years ago, naturopathic medicine has been an eclectic system of health care. This characteristic has allowed it to adopt many of this century's more effective elements of natural and alternative medicine as well as to adopt conventional medicine's basic and clinical sciences, diagnostics, and pharmacology. Through all of this eclecticism, naturopathic medicine has always identified the Latin expression *vis medicatrix naturae* (the healing power of nature) as its philosophical linchpin.

However, the expression *vis medicatrix naturae*, by itself, does not provide a clear picture of naturopathic medical philosophy or an understanding of the practice of naturopathic medicine in all of its varied forms. With the profession's history of eclecticism, no two practitioners treat any individual patient exactly alike. This situation has its advantages (e.g., individualization of each patient's care, more therapeutic options) but also makes it difficult to perceive the profession's philosophic cohesiveness. Another major disadvantage of this eclecticism is the difficulty in developing consistent practice standards.

To attempt to solve this problem, the modern profession has articulated a general statement of naturopathic principles that expand on *vis medicatrix naturae* (Box 5-2). However, to gain a more in-depth understanding of naturopathic medicine, one must discuss medical philosophy in general.

MEDICAL PHILOSOPHY

The issues fundamental to a discussion of medical philosophy have changed little since naturopathy first appeared as a distinct profession at the end of the nineteenth century. What has changed is the level of understanding of the biological process and the language of science. Most people who study the early writers on naturopathic medical philosophy quickly get lost in the archaic language and arguments used to justify the theories. This chapter translates these concepts and issues into modern terms.

Vitalism Versus Mechanism

Historically, there have been two main medical philosophies, those of vitalism and mechanism. Their origins can be traced to the Hippocratic writings of ancient Greece. Throughout history, the line separating these two schools of thought has not always been clear, but their philosophical perspectives have

generally been in opposition. The conflicting goals and philosophical foundations of these two concepts remain relevant as the modern practices of conventional and alternative physicians come into conflict. As will be seen, the foundations of naturopathic medical philosophy are found in vitalism. However, naturopathy also recognizes the practical value of the mechanistic approach to health care.

Mechanism

Up to the early part of the twentieth century, there was considerable debate over the issue of vitalism versus mechanism in the field of biology. The mechanists, or materialists, maintained that the phenomenon of life could be explained exclusively as the product of a complex series of chemical and physical reactions. They denied the possibility that the animate had any special quality that distinguished it from the inanimate. It was their contention that the only difference between life and non-life was the degree of complexity of the system.

Mechanism has several other distinctive characteristics. Its most obvious is that it is reductionistic. *Reductionism* is often used as a synonym for *mechanism*. Mechanistic science is also characterized by an emphasis on linear causality. Without this emphasis on reductionism and linear causality, Western science and medicine would probably have not been so successful. As the twentieth century advanced, each new discovery in biological and medical science reinforced the arguments for mechanism, until, by the middle of the century, the biology community had almost exclusively embraced the philosophy of mechanism.

Mechanism is the philosophical foundation of biomedical science and conventional medicine. It is especially visible in the treatment modalities of surgery and most pharmaceuticals. Mechanistic medicine identifies disease and its accompanying signs and symptoms as simply the result of a disruption of normal chemical reactions and physical activities. Such disruptions are caused by the direct interference in these reactions and activities of a "pathogenic agent." (For the purposes of this discussion, the expression pathogenic agent refers to any known or unknown etiologic agent, influence, or condition; examples are microbial agents, autotoxins, genetic defects, environmental toxins, non–end-product metabolites, and physical and emotional stress and trauma.) A living organism, then, is simply a very complex machine that, due to external agents and influences and "wear and tear," breaks down. Because the signs and symptoms of disease are thought to be due only to these mechanical disruptions and interference with reactions, they are considered to be completely destructive phenomena and are therefore to be eliminated. Disappearance of the signs and symptoms indicates that the pathogenic agent and its resulting disease have been eradicated or, more likely, controlled. The goals of mechanistic medicine tend to be the quick removal of the signs, symptoms, and pathogenic agent.

Mechanistic medicine is being practiced in cases in which the intention of the therapy is to intervene in the perceived mechanism of the disease and/or to relieve the symptoms. Examples would be the use of antihistamines to relieve rhinitis, vitamin B_6 to help carpal tunnel syndrome, emergency care for traumatic injuries, coronary bypass surgery for blocked arteries, and insulin in juvenile-onset diabetes. Mechanism is also being used when an identified pathogenic agent is directly attacked or eliminated, for example, the use of antibiotics or the isolation of a patient from a particular allergen. Clearly, mechanistic medicine can be very effective in achieving its goals. In the presence of modern medical technology, it is easy to see how this philosophy came to dominate biology, medicine, and the attention of the public.

However, the unsolved problems of mechanistic medicine—particularly those of chronic degenerative disease; authoritarianism, which alienates patients from responsibility for their own health; and the rising cost of health care—suggest that there are limits to the mechanistic perspective and explain why vitalism has not disappeared and is in resurgence.

BOX 5-1 Naturopathic Modalities

Naturopathic physicians are trained to use a number of diagnostic and treatment techniques. These modalities include the following:

- *Diagnosis.* All of the conventional clinical laboratory, physical diagnosis, and imaging (e.g., radiography) techniques, as well as holistic evaluation techniques
- *Counseling.* Lifestyle, nutritional, and psychological
- *Natural medicines.* Nutraceuticals (i.e., all food constituents, constituents of biochemical pathways, etc.), botanical medicine, and homeopathy
- *Physical medicine.* Hydrotherapy, naturopathic manipulative therapy, physiotherapy modalities, exercise therapy, and acupuncture
- *Family practice.* Natural childbirth, minor surgery, natural hormones, biologicals, and pharmaceuticals

BOX 5-2 The Principles of Naturopathic Medicine

The Healing Power of Nature: *Vis Medicatrix Naturae*
Nature acts powerfully through healing mechanisms in the body and mind to maintain and restore health. Naturopathic physicians work to restore and support these inherent healing systems when they have broken down by using methods, medicines, and techniques that are in harmony with natural processes.

First Do No Harm: *Primum Non Nocere*
Naturopathic physicians prefer noninvasive treatments that minimize the risks of harmful side effects. They are trained to know which patients they can treat safely and which ones they must refer to other health care practitioners.

Find the Cause: *Tolle Causam*
Every illness has an underlying cause, often in aspects of the lifestyle, diet, or habits of the individual. A naturopathic physician is trained to find and remove the underlying cause of a disease.

Doctor as Teacher: *Docere*
A principal objective of naturopathic medicine is to educate the patient and emphasize self-responsibility for health. Naturopathic physicians also recognize and employ the therapeutic potential of the doctor–patient relationship.

Treat the Whole Person
Health or disease comes from a complex interaction of physical, emotional, dietary, genetic, environmental, lifestyle, and other factors. Naturopathic physicians treat the whole person, taking all of these factors into account.

Preventive Medicine
The naturopathic approach to health care can prevent minor illnesses from developing into more serious or chronic degenerative diseases. Patients are taught the principles with which to live a healthy life; by following these principles they can prevent major illnesses.

Vitalism

The philosophy of vitalism is based on the concept that life is too well organized to be explained simply as a complex assemblage of chemical and physical reactions (i.e., a living system is more than just the sum of its parts). This is in contrast to the mechanist's contention that "the only difference between life and non-life is the degree of complexity."

Throughout the nineteenth century, the debate between vitalism and mechanism was carried out mostly by biologists and, in medicine, between the "regular" doctors and those doctors who would now be called alternative. In the medicine of the nineteenth and early twentieth century these would have been homeopathic, hydrotherapy, nature cure, and eclectic doctors—all medical doctors with equivalent credentials under the laws of the time. Although the specific terms of "vitalism" and "mechanism" were not necessarily the nomenclature of their debate, the perspectives were the same.

Interestingly, through most of the nineteenth century this debate within the medical community was distinctively not based on science as we currently think of it. The "regular" doctors of the era, as represented by the American Medical Association, were still strongly influenced by Galen's theory of disease of the four humors with its imaginary anatomy and physiology, bleeding, leeches, mercury, and other horrific treatments. Both the homeopaths and eclectic doctors argued based on empirical evidence; on the other side, the regular doctors argued based on a dogmatic theory that was more than 1500 years old and unsupported by any evidence. Harris Coulter produced the seminal work on this debate in his three-volume book *The Divided Legacy*.

The debate between vitalism and mechanism within the field of biology is well documented within the biology journals of the time. This was an era of amazing discoveries about how life functioned. Naturally, this is where the focus of this debate took place for biologists. As the secrets of cellular metabolism were revealed, this debate lurched from one specific argument to the next. The issue was where in the living organism did "God" have direct control. For example, at one point it was argued that the "seat of the soul" was the cell. As the cell was better understood, the place that was the point of God's intervention was postulated to be the nucleus. As research further revealed how the organelles functioned, the vitalistic biologists gave up ground until vitalism as a distinct philosophy in biology was finally abandoned.

The error that doomed the vitalistic oriented biologists was that they were all reductionistic in the same way as the mechanistic biologists. Reductionistic science seems completely able to learn how life functions from a biochemical and biophysical perspective. Eventually, all of the individual chemical and physical reactions that are found in the processes of life will probably be identified. However, the vitalistic biologists missed the most essential aspect of vitalism: *holism*.

In naturopathy's early years there were few interactions between it and the academic and research worlds. The great authors and practitioners came to naturopathy through "conversion," in other words, most had been cured of some health problem by a natural cure and felt naturopathy and curing the sick was now their calling. There is no evidence that these naturopaths even knew that this debate between vitalism and mechanism was going on in the biology literature. Research in this early era of naturopathy consisted of observing nature and applying these observations to treating patients. This led to a deep appreciation of "nature's" desire for balance and order (what a physiologist would call homeostasis). This holistic perspective, combined with the results of the naturopathic treatments, was the empirical evidence that drove their understanding of health and disease. It was only in the later half of the twentieth century that the field of naturopathic medicine began to converge with the academic and research worlds. Since the 1970s this convergence has moved at breakneck speed, until today there is no longer any real distinction (although this is not evident in some of the politically motivated diatribes against the field of natural medicine). However, by this time the academic and research worlds had long since forgotten about vitalism.

An organism's unique complexity—as demonstrated by its ability to grow and develop, respond to stimuli, reproduce, and repair itself—requires a level of organization and coordination that suggests a distinct quality that is not readily explained by mechanism. This is studied extensively by all medical students in physiology class as the "normal" homeostatic process common to all living organisms. However, the tendency in conventional medical school is to put the concept aside when the student moves on to study pathology and the clinical sciences. Yet, up to the point of death, maintaining homeostasis is a prime, if not the primary, driving force in all living organisms. To think that homeostasis is only an important factor in "normal" physiologic processes and has no relevance in pathology is to ignore all of the basic sciences. All life is attempting to return to this ideal state whenever injured or ill. The only point in the life cycle that an organism is no longer "trying" to maintain homeostasis is death.

Reductionistic science has done a wonderful job elucidating the functions of the various components of life, but it tends to focus the researcher and the physician on the disease process as an isolated phenomenon rather than the result of a complex reaction of the whole organism to a pathologic agent. Fortunately, the debate between the vitalistic and mechanistic perspectives in the modern era focuses on the more relevant and holistic general concepts. Although modern vitalism is inherently holistic in its view, there is no conflict with the findings of biomedical science. What is significant is not the individual biochemical or biophysical reactions, but the fact that they are all coordinated to such a degree as to produce the special activities of a living organism. Because there is no inanimate counterpart to this level of complexity and organization, homeostasis is the most dramatic general argument in favor of vitalism.

A less dramatic argument supporting the vitalistic perspective is the "problem of entropy." Entropy is the tendency of any closed system to find equilibrium, that is, the state of least organization. In other words, systems tend to run down and become less complex over time. In defiance of this universal rule, life, up until the point of death, consistently creates more complex systems out of simple ones. To do this, life actively pursues external matter and energy to incorporate into itself while also selectively eliminating by-products from its utilization of this matter and energy.

When the problem of entropy is examined on the molecular level, the same individual chemical processes and elements may be found in both animate and inanimate systems. In the inanimate system, however, there is a constant move toward a state of chemical equilibrium. This type of system cannot maintain an unstable chemical state and always seeks stabilization. Even after the addition of external exciting energy, the system returns to the simplest, least reactive state possible. The animate system is virtually the opposite. It is continuously in a state of dynamic chemical instability, actively seeking energy to maintain this instability and consistently moving to more complex and more organized states (and back again). It is only at the onset of death that an animate system begins to move toward equilibrium, and, of course, then it is no longer animate.

The third general argument in favor of a vitalistic view of life is evolution. For evolution to exist as a force in nature, generations

of living organisms have to survive long enough to grow, reproduce, and then evolve. For this survival to take place, the organisms' homeostatic and repair processes must be consistently directed toward maintaining a state of balance with the external environment (i.e., health). Any organism that does not behave biochemically and physiologically in this manner dies and cannot evolve. Thus the phenomenon of evolution, as the action of countless living organisms over eons, multiplies life's antientropic quality and is incompatible with a mechanistic view of living systems.

These easily observable examples of life's "special quality" suggest an "organizing force" that goes beyond what is possible from mere chemistry. This quality that makes life unique should not be mistaken as a metaphysical concept, although an argument for or against such concepts is not intended here. The point is only that vitalism is a medical philosophy based on observable scientific phenomena. Unfortunately, a definitive definition of this quality (in the old literature called the "vital force," defense mechanism, or simply "Nature") will have to wait for vitalistically or holistically oriented researchers. Reductionistic research has not provided much clarification of these special qualities of life—just ask a modern reductionistic biologist to explain how homeostasis works. They can describe what happens on a biochemical and biophysical level but they cannot describe why it happens.

At this point in the discussion, not many mechanistic practitioners would have reason to be uncomfortable. However, the conflict becomes evident with examination of the premises upon which the practice of vitalistic medicine is based. What truly separates vitalism from mechanism and makes it useful as a medical philosophy is its perspective on disease and its associated symptoms.

Meaning of Disease

Vitalism maintains that the pathogenic agent does not directly cause most symptoms accompanying disease; rather, they are the result of the organism's intrinsic response or reaction to the agent and the organism's attempt to defend and heal itself. Symptoms, then, are part of a constructive phenomenon that is the best "choice" the organism can make, given the circumstances at any particular time.

These symptoms can be further described as arising from two situations. The first and most common situation is when the symptoms are from what could be called a "healing reaction"—the organism's concerted and organized attempt to defend and heal itself (i.e., the organism's homeostatic process). These healing reactions produce what can be called "benign symptoms." Examples are fever and inflammation in infections, almost any reaction of the immune system, and many of the symptoms of chronic disease.

This interpretation of symptoms is generally ignored by mechanism. Instead, it views a symptom as the result of a destructive process and focuses on intervening by relieving the symptom or manipulating the pathologic mechanism. Mechanistic medicine is therefore most often working contrary to homeostasis and the organism's attempt at healing (this is usually its intent). When this therapeutic approach is effective, vitalists call the result a "suppression" (Box 5-3). This approach to health care is so pervasive that

BOX 5-3 Cure, Suppression, Palliation, and Healing

Cure: A cure occurs when:
(a) a treatment is given to the person;
(b) the signs and symptoms of the disease go away;
(c) the treatment is removed and the signs and symptoms stay away; and
(d) the whole person is healthier and less likely to get sick than before the illness.

This is almost always going to occur only when the whole person was treated, and not just the disease or its symptoms. Palliation and suppression never lead to cure in and of themselves.

Palliation: Palliation occurs when:
(a) a treatment is given for the disease;
(b) the signs and symptoms of the disease go away; but
(c) when the treatment is removed the signs and symptoms return.

The symptoms of the disease are simply being controlled (not cured) as long as the treatment is continued.

It is a classic error of many practitioners and patients to equate palliation with moving towards cure. Palliation is on the opposite end of the spectrum as cure and is closer to suppression. Palliation can be useful, but in and of itself, never leads to cure—other more vitalistic and holistic interventions are necessary and may be as simple as changing to a healthier diet, removing some obstacle to recovery, or reducing stress, or as complex as classical homeopathy or traditional Chinese medicine. When palliation is used over a long enough time, suppression is the natural consequence.

Palliation is the most common result of almost all health care interventions. This is especially true of conventional medicine but also true for much of alternative medicine as well. Unfortunately, both the practitioner and the patient's expectations are frequently satisfied with palliation. This is the most frustrating aspect of modern health care, whether conventional or alternative. Too few people are striving for a cure.

Suppression: Suppression is when:
(a) a treatment is given for a disease;
(b) the signs and symptoms of the disease go away;
(c) the treatment is removed and the signs and symptoms stay away; but
(d) the whole person is less healthy.

Although the symptoms of concern are better, the whole person is worse, which leads to more and worse disease in the future. In conventional medicine suppression is often a goal. Alternative medicine tries for a higher standard, but because palliation is often what happens, suppression can occur here, too.

Suppression frequently occurs because a treatment is given for a symptom or disease rather than the whole person being treated. Suppression leads later to another more invasive illness. An example is when steroids are given to suppress eczema and later asthma develops. If at this later point the person is given a treatment that is curative, there will be a return of the eczema as the asthma gets better.

Healing: Healing is what a living organism (body–mind) does, or attempts to do, for itself. A treatment can only:
(a) control signs and symptoms (palliate or suppress);
(b) support life in a crisis (palliate or suppress);
(c) attack an invading organism such as bacteria or remove a pathologic agent such as a toxin or allergen (palliate);
(d) mechanically repair tissues that have been damaged or are malformed (palliate); or
(e) support and/or stimulate the organism's innate healing processes while the body–mind does the work of healing itself (cure).

Curative treatment involves stimulating the whole organism to heal itself. The palliation and suppression of symptoms does not help to stimulate self-healing. Palliation tends to create the opposite effect and suppression actually gets in the way of the whole body–mind's efforts to self-heal.

most people, lay and professional alike, still think nothing of suppressing mild fevers with antipyretics.

In contrast, vitalism considers these symptoms to be the product of a constructive phenomenon and therapeutically stimulates and encourages this directed healing process. Rather than simply trying to eliminate a pathogenic agent, as mechanistic therapy might, vitalism focuses more on augmenting the organism's resistance to that agent. That is not to say that vitalists object to removing the agent, only that it should be done in the context of simultaneously increasing resistance (in other words, decreasing susceptibility). The importance of this approach becomes evident when one recognizes that disease is only possible when both a pathogenic agent and a susceptibility to that agent are present.

Healing reactions can take several forms. In the first type, an organism's response to a pathogenic agent does not produce symptoms. When the organism is capable of easily defending itself from the agent, no symptoms are perceivable. This is a common homeostatic process and is demonstrated when a potential pathogen, such as β-hemolytic streptococcus, is cultured from a healthy person's throat. However, when the organism is more susceptible or the relative strength of the pathogenic agent is greater, a threshold is reached and symptoms become perceivable. Successful healing reactions of this type include vigorous acute diseases that quickly resolve. The early naturopaths would have called these acute reactions "healing crises." As the susceptibility of the organism increases relative to the strength of the pathogenic agent, there is a greater likelihood that the healing attempt will not be successful. When such a reaction is unsuccessful but vigorous, death may result, unless there is timely application of vitalistic or mechanistic therapy. Examples of this situation are acute bacterial meningitis and cholera.

When the healing attempt is feeble and therefore ineffective, the reaction usually goes into the "chronic disease" stage. Vitalists observe that suppression seems to increase the likelihood that the reaction will be forced to go into such a chronic stage. In this situation the reaction is "smoldering," and most often the organism cannot overcome the pathogenic agent unassisted. It just "holds its own," and as the organism's general health decreases over the years, the reaction gradually degenerates, producing symptoms that become less benign as it moves to an end-stage pathology. Palliating the symptoms during this phase of the disease contributes to the declining health over time because palliation means that the underlying susceptibility or problem is not being addressed in a curative manner. If the organism can be therapeutically stimulated to produce a more vigorous healing reaction, it can often successfully complete the original healing attempt. This augmented reaction is another example of a naturopathic healing crisis and would also be called an "aggravation" by the vitalists who practice homeopathic medicine.

Intervening mechanistically by relieving symptoms does little to stimulate or encourage the healing response; it usually actually inhibits the healing response. In contrast, vitalistic therapies can be very effective in helping these healing reactions, because the goals of such therapies are precisely the same as those of the organism. Thus, it is thought that vitalistic medicine works because, by honoring this process and thereby strengthening the whole organism, it encourages a more effective healing effort. Ideally, the organism is then able to accelerate and complete its reaction against the pathogenic agent, leading to the permanent disappearance of the symptoms as it returns to a state of health.

It would be naive to say that every stage of the healing reaction is positive and in the best interest of the organism or that no symptoms should be palliated. The modern vitalist acknowledges that palliative intervention is sometimes necessary. In contrast, it is important to note that routine mechanistic intervention can encourage its own worst case scenarios. When mechanistic therapies successfully suppress an organism's chosen healing reaction, a less effective and less desirable response is often produced. Therefore, when suppression occurs, it can lead to a more complicated medical situation. Consequently, the very practice of mechanistic medicine tends to reinforce its practitioner's conviction that such intervention is usually necessary. It should be noted, however, that not all mechanistic intervention leads to suppression. It happens less often when the pathogenic agent can be readily eliminated, such as the use of an antibiotic in nonrecurring acute bacterial infections, or when relatively noninvasive therapies are used, such as natural medicines.

The second type of symptom-producing situation occurs when the organism produces symptoms in response to an organic lesion that arises from the direct pathologic influence of a pathogenic agent. These could be called "morbid symptoms," examples of which are symptoms from the mass of an invasive tumor, shortness of breath from emphysema, and pain of an injury or myocardial infarction. It should be mentioned that even these symptoms are the result of the organism's overall effort to maintain homeostasis, and benign symptoms are also often present. In addition, a morbid symptom is not necessarily produced for a negative reason. For instance, pain is valuable as an indication of tissue damage. As can be seen, many, if not most, of these situations involve end-stage disease. Here mechanistic therapies can be very positive when the goals of the therapy do not conflict with those of the organism.

There are instances when invasive mechanistic intervention will probably be required to save "life and limb." These include such conditions as birth and genetic defects, serious traumatic injuries, crisis situations, overwhelming infections, and many malignancies. Unfortunately, mechanistic intervention does not guarantee a successful outcome either. Even in these situations, however, the effectiveness of vitalistic and natural therapy should not be underestimated, and their concurrent use will certainly augment any mechanistic intervention.

The concept of benign and morbid symptoms can be a useful tool to help the understanding of the healing and disease processes, but in many situations, it may not be possible to categorize the type of symptoms produced. A rough rule of thumb, however, would be that virtually all symptoms accompanying reversible or functional diseases are benign. In contrast, many of the symptoms associated with traumatic injury and end-stage pathology would be morbid symptoms.

Scientific Medicine

Although mechanism and vitalism represent opposing perspectives, the systems of medicine that represent these philosophies can be successfully tested and examined with the scientific method.* That is not to say that the philosophy of vitalism has been unquestionably proven—only that the validity of vitalistic

*A thorough review of all health care modalities in use today reveals a category that could be called "esotericia." Although the category is not historically relevant to this discussion of medical philosophy, and its brief mention is not intended as an argument for or against "legitimacy," esotericia would include such things as prayer, faith healing, psychic healing, healing touch, touch for health, and medical dowsing. Generally speaking, the actual operator of the therapy must call on God or have some special endogenous skill or "power" that goes beyond intellectual knowledge. These modalities are all "operator-dependent" and cannot be examined separately from the practitioner—thus greatly increasing the difficulty of their scientific verification.

interventions can be scientifically demonstrated. If a therapy can be proven effective, the effectiveness implies the accuracy of the philosophy upon which it is based. Unfortunately, very few of the vast resources of the biomedical community have been directed toward investigating vitalistic medicine.

Conventional medicine, as the dominant health care system and a representative of mechanism, has claimed for itself the title "scientific medicine." However, it is inherently no more or less scientific than vitalistic medicine. A system is scientific only when it has met the criteria of the scientific method. This method requires the collection of data through observation and experimentation and the formulation and testing of hypotheses. Nonprejudicial science can effectively study any system, but the researcher must understand the system's particular paradigm. Experiments on a vitalistic therapy based on a reductionistic and mechanistic model are not going to be constructed to show success, or if they do show success, it will be entirely fortuitous.

The criteria of the scientific method can be met by vitalistic medicine, but only when the researchers recognize that it cannot be studied as though it is reductionistic or based on a simplistic model of linear causality. When the experimental model acknowledges the complexity of a living system in a social context (i.e., holism and circular causality/feedback loops), vitalistic medicine proves to be both verifiable and reproducible and, thus, scientific. Unfortunately, because of its current political and economic dominance, conventional medicine is in the position to dictate (through economic and publication control) that research and, therefore, the scientific method will be applied primarily to itself. The result is that most conventional practitioners dismiss vitalistic medicine, along with all alternatives, as unscientific. Ironically, most vitalistic physicians also have extensive training in mechanistic and/or conventional medicine. Generally, they are capable of practicing mechanistically and do so to greater or lesser degrees.

NATUROPATHIC PHILOSOPHY

Vis Medicatrix Naturae

Naturopathic physicians assert that all true healing is a result of *vis medicatrix naturae* (the healing power of nature). Unfortunately, some people in the field of alternative medicine (including some naturopathic physicians and students) have mistakenly translocated this concept to the therapy. These practitioners tend to operate as though this "healing power" is an intrinsic property of the natural therapy or medicinal substance itself. In contrast, proponents of vitalism and naturopathic medicine have always understood that the "healing power of nature" is an inherent property of the living organism. *Vis medicatrix naturae* is the living organism's "desire" and ability to heal itself. As mentioned, the homeostatic process best exemplifies this.

Historically, naturopathy is a vitalistic system of medicine. However, over the last 120 years its eclecticism has allowed it to incorporate a number of therapies that can function mechanistically. What makes these mechanistic therapies acceptable, given naturopathic medicine's vitalistic foundation, is the emphasis on meeting each patient's pragmatic health care needs. So the application of *vis medicatrix naturae* in practice is constantly adjusted depending on the situation at hand.

Ideally, naturopathic practice involves only the use of therapies that support the organism and encourage its intrinsic healing process to work more effectively while avoiding the use of medicines and procedures that interfere with natural functions or have harmful side effects. Natural medicines and therapies are therefore preferred, because when they are used properly and in appropriate circumstances, they are the least harmful, least invasive, and best able to work in harmony with the intrinsic natural healing process. In addition, their constituents have been encountered in nature for millions of years. This long period of exposure has enabled the body to develop metabolic pathways capable of effectively utilizing, processing, and detoxifying these medicines.

The total organism is involved in the healing attempt, so the most effective approach to diagnosis and treatment is to consider the whole person. In addition to physical and laboratory findings, important consideration is given to the patient's attitude, psychological and spiritual state, social circumstances, lifestyle, diet, heredity, and environment. Careful attention to each person's unique individuality and susceptibility to disease is critical to the proper evaluation and treatment of any health problem.

Naturopathic physicians contend that most disease is the direct result of the ignorance and violation of what would be traditionally called "natural living laws." These general lifestyle rules (including diet) are based on the concept that there is an environment (both internal and external) that optimizes the health of an organism. Analysis of the lifestyles of Paleolithic and healthy primitive and modern cultures gives naturopathic physicians and their progenitors many clues as to what a healthy lifestyle should involve.

Throughout most of modern history, biomedical science has focused primarily on researching the sick. Recently it has finally begun to evaluate what constitutes a healthy lifestyle. To no one's surprise, this lifestyle looks like the same one advocated by naturopaths for the last 120 years. A healthy lifestyle could be generalized to include the following:

- Consuming natural unrefined foods
- Getting adequate amounts of exercise and rest
- Living a moderately paced lifestyle
- Having constructive and creative attitudes
- Connecting to other people socially
- Being present to the spiritual aspects of life
- Avoiding toxins and polluted environments
- Maintaining proper elimination

It is also important to control these areas during illness to remove as many unnecessary stresses as possible and to optimize the chances that the organism's healing attempt will be successful. Therefore, patient education and responsibility, lifestyle modification, and preventive medicine are fundamental to naturopathic practice.

Although the practice of naturopathic medicine is grounded in *vis medicatrix naturae*, it also recognizes that mechanistic intervention in the disease process is sometimes efficacious and, at times, absolutely necessary. Therefore, naturopathic physicians treat patients with a wide variety of vitalistic and mechanistic therapeutic modalities. It is the circumstances and the goal of the therapy that ultimately determines which approaches are utilized. Naturopathic physicians have a long-standing tradition of integrating the best aspects of traditional, alternative, and conventional medicine in the interest of the patient. As appropriate, patients are referred to other health care practitioners. Whenever possible, every effort is made to use all treatment techniques in a manner that is harmonious with the naturopathic philosophy.

Natural Medicines and Therapies

Traditionally, medicines administered and prescribed by naturopathic physicians have been primarily natural and relatively unprocessed. Four categories of natural medicines can be defined.

The first consists of substances found in nature that have been only minimally processed. Examples include, but are not limited to, foods, clean air and water, and whole herbs. The early "nature cure" practitioners used this category primarily. The second category involves agents extracted or made from naturally occurring products. Although these medicines have undergone processing, their constituents are still in the form found in the original natural substance. These first two types of natural medicinal substances have synergistic constituents that allow their use at lower doses with a resultant broader and safer therapeutic index. Examples of this category are tinctures and other botanical extracts, homeopathic medicines, glandular extracts, and other substances of animal origin.

The third category of natural medicines comprises those highly processed medicinal substances that are derived from a natural source. Often everything has been removed from such substances but the identified active ingredient, and they no longer have any synergistic constituents. Examples of these are the many new nutraceuticals made from plant substances, constituents of biochemical pathways, enzymes, amino acids, minerals, vitamins, and other food extracts.

The fourth category that may be considered natural are those manufactured medicines that are presumed to be identical to naturally occurring substances. They have the advantage of being less expensive and are typically available in higher concentrations. Examples of these manufactured natural medicines include bioidentical hormones, synthetic vitamins, and analogues of plant and animal constituents. However, their use is a compromise because:

- It is difficult to determine whether they are the equivalent of the natural product.
- They lack natural synergistic components.
- They include contaminates from the manufacturing process; these contaminates are often chemically and structurally similar to the desired medicine but generally interfere with the normal pathways rather than enhance them.

Naturopathic physicians also use many natural therapies. What makes a therapy natural is that it is derived from a phenomenon of nature and is used to stimulate the body to heal itself. Examples of these phenomena are air, light, heat, electricity, sound, and mechanical force. Some of these natural therapies are mechanical and manual manipulation of the bony and soft tissues (naturopathic manipulative therapy), physiotherapy modalities (e.g., electrotherapy and ultrasound), hydrotherapy, and exercise therapy. Naturopathic physicians also use lifestyle modification, counseling, and suggestive therapeutics. These therapies are all discussed in more detail in other chapters.

Family and Specialty Practice

Naturopathic physicians, like other types of primary care providers, develop practices that meet their personal interests and skills. Although most are engaged in general and family practice, many have also specialized in particular therapeutic modalities and/or types of health problems. In all situations, however, the emphasis is still on treating the whole person. The practice of family medicine requires the use of some medicines, techniques, and devices that are not natural but belong among the comprehensive family practice services offered by the naturopathic profession.

In the modern era of naturopathic medicine many states have expanded the scope of practice so that naturopathic physicians now practice much like other primary care practitioners with pharmaceutical prescribing rights. However, naturopathic physicians generally approach the use of pharmaceuticals differently than conventional physicians. They are seen as temporary interventions to be used to support the patient while other, more vitalistic natural therapies are used to help the patient recover his or her health with the ultimate goal of no longer needing the pharmaceutical.

Many naturopaths have also developed advanced expertise in different natural therapeutic modalities. These practitioners have usually invested in postgraduate training, such as that available through residencies. Three therapeutic specialties that merit mention are natural childbirth, acupuncture, and homeopathy. There is also a growing trend of specializing in organ systems (e.g., gastroenterology) or diseases (e.g., cardiology).

THE PHILOSOPHICAL CONTINUUM

When the various healing systems are examined and placed on a philosophical continuum, mechanism and vitalism are on different ends of the same health care spectrum. Both ends of this health care continuum have their strengths and weaknesses. Mechanistic medicine is effective for trauma, crisis care, end-stage disease, and many acute disorders. However, it is essentially a failure for chronic disease. Conventional medicine considers most chronic diseases incurable. Vitalistic medicine, in contrast, has its most dramatic successes with chronic disease and is effective with many kinds of acute disease. It is not very effective with trauma and crisis care or with end-stage disease, although it can be a very useful complement to conventional medicine. As can be seen, both ends of the health care spectrum are necessary if every patient's health care needs are to be met.

Although aspects of naturopathic medicine (e.g., constitutional hydrotherapy) and conventional medicine (e.g., chemotherapy) represent the archetypes of vitalism and mechanism, the space between the ends of this spectrum is a gray area within which both naturopathic and conventional physicians operate on a continual basis. Naturopathic physicians integrate vitalistic therapies with mechanistic therapies, but it is not possible for everyone to be experts in everything. The vast majority of naturopathic or conventional physicians cannot learn and competently practice all types of health care. Consequently, to effectively meet society's health care needs, it is necessary to create an integrated health care system. Such an integrated system would have both vitalistic and mechanistic practitioners working together in the same clinical settings.

The trends of popular culture and biomedical science that are finally beginning to study alternative medicine suggest that the creation of an integrated health care system is now under way. However, it takes no great skill for a mechanistic medical doctor to switch from giving a synthetic drug for a disease to giving a natural medicinal substance (both mechanistically oriented interventions). If naturopathic medicine becomes just another mechanistic system using natural medical substances to treat disease (instead of a system identified with treating the whole person vitalistically), it will lose its unique niche in an integrated health care system. To survive and thrive in this new environment, naturopathic medicine must keep its vitalistic roots. With a thorough grounding in *vis medicatrix naturae*, modern naturopathic medicine will flourish and achieve a leadership position as the dominant health care paradigm shifts to the integrated medicine of the future.

CONCLUSION

The practice of naturopathic medicine can be summarized most simply as helping the body–mind heal itself in the least invasive, most fundamentally curative manner possible. This approach is

not tied to any particular therapy or modality, but rather is oriented to a rational blend of vitalistic and mechanistic principles working with the whole person and educating the patient in the ways of health.

As naturopathic knowledge of health and disease grows, new therapies and approaches to health care will be added as they satisfy the principle of *vis medicatrix naturae*. With integration of the larger health care system, naturopathic medicine's place is assured as the profession that truly understands each unique human being's power to heal.

CHAPTER 6

Placebo and the Power to Heal

Peter W. Bennett, ND, RAc

INTRODUCTION

As living organisms, we have evolved with an innate capacity for self-healing. Naturopathic physicians have always relied in the clinical setting on this self-healing capability of the individual. The healing power of the body, the "life force," is a cornerstone of naturopathic philosophy and treatment. The "inner" power to heal is one of the great mysteries of medicine, and it behooves us as physicians, regardless of our licensing body, to understand the biology and physiology that surround the processes that guide and control this phenomenon. Following this logic, a central problem to be explored and considered is that placebo response has shown medical science that the mind of a patient has a powerful role in therapy. Because the definition and understanding of the human mind challenge a consensus of our collective insight and understanding, it is natural that the function and use of placebo is an area of myth and misunderstanding rather than an area of wisdom and insight.

As time marches on, medicine has failed to stimulate and utilize the subliminal healing capacity of the mind. A recent review of placebo literature in *Lancet*[1] concluded that the placebo effect has a complex physiologic multisystem dimension and should be encouraged in the clinical situation to optimize health and healing; a summary reached by this author 25 years ago. In November 2000, 17 health centers and agencies gathered together for 3 days to explore the science of self-healing hidden in the power of placebo. This conference focused on the powerful mind–brain physiology of placebo and its potential for affecting the course of human disease.[2] One of the conclusions of the conference was that the "placebo response" has potential use for medical application and needs further exploration.

Research has shown that the impressions and thoughts in a patient's mind and the attending physician's intention have a measurable effect on the health of the patient. The ability of the patient's mind to affect the process of virtually every disease has been well documented,[3,4] and the internal mechanisms and pathways by which the mind can positively or negatively affect the immune and healing processes has been investigated in the scientific literature of psychoneuroimmunology.[5,6] As the body of knowledge documenting the critical role of the patient's psyche in the therapeutic environment has grown, it has become increasingly important for all schools of medicine to teach the healing potential of the human mind.

Conventional medical thinking has turned its opinion of placebo from that of a nineteenth-century pejorative to a concept that sums up the complex mind–body interactions affecting the power of people to heal.[2] Unfortunately, the most modern abuse of the concept of placebo comes from biased critics of alternative medicine who have chosen to label the beneficial effects of these therapies as merely from placebo. These critics dismiss the science of natural healing as an imaginary phenomenon and the last resort for quack doctors who have no real medical treatments to offer their patients.[7]

The most interesting aspect of placebo literature is exploration of the extent of the potential of the mind to influence human health. The "power of placebo" draws upon the innate ability of the body to spontaneously heal itself, a fundamental principle of naturopathic medicine. This point separates the care delivered by naturopathic physicians from the pharmaceutical and surgical approaches of current medical "standard of care" procedures. If common medical texts on internal medicine or ambulatory care are examined, the word "healing" is not found in the index. Except for the diagnostic evaluation of "self-limiting diseases" and "spontaneous

regression," the ability of the human organism to self-right and repair from a state of acute or chronic disease is not explored in modern medicine except under the designation "placebo response." The placebo response, therefore, represents all the "unknown" variables that conspire to heal a patient despite pharmaceutical and surgical intervention. Although it seems to be a natural area to develop in clinical and hospital settings, the fundamental separation of mind and body in conventional medical thinking may be slowing down a standardization of care that actively engages the hopes and beliefs of all patients undergoing treatment.

PLACEBO RESPONSE

Placebo response represents the power of the mind, through intention, to effect (1) a change in oneself, (2) a change in those around one, and (3) a change in the environment in which one lives. Intention has been observed to affect machines[8] and remote biological systems.[9] Distantly influenced systems include another person's electrodermal activity, blood pressure, and muscular activity; the spatial orientation of fish; the locomotor activity of small mammals and the rate of hemolysis of human red blood cells. Prayer, an example of intention, has been extensively studied as a therapeutic healing modality.[10] One study showed a dramatic result in cardiac intensive unit recovery when patients were prayed for by someone at a distant location.[11] Patients in this study were 5 times less likely to require antibiotics, 3 times less likely to experience pulmonary edema, 12 times less likely to require endotracheal intubation, and significantly less likely to experience cardiac mortality.

Our biological systems must conform to the laws of physics. Modern physics has investigated the effect of an observer on the system observed. It has been shown that an electron will acquire a definite axis of measurement in the process of measurement. Bell's theorem supports the idea that our universe consists of particles unified instantly as an indivisible whole; our biological homeostatic systems cannot be analyzed in terms of independent parts. The interconnected nature of our biological systems has been known for thousands of years; the ancient Buddhist concept of "interdependent phenomena" accurately describes this paradigm.

Our current medical system has not shifted with the developments in modern physics. These modern ideas of biological systems are diametrically opposed to Cartesian paradigms that our internal and external environment consists of separate parts joined by local connections. Medicine must take a "quantum leap" to catch up with the knowledge we possess about our environment through quantum physics. We can see clearly that it is impossible for a doctor to observe a patient without the observation's affecting the health of the patient.

Pierre Teilhard de Chardin postulated, and Rupert Sheldrake proved, the possibility of a "morphogenetic field" for the subliminal communication to all members of our species.[12] The effect of human thought on other members of society has been described in human society since the beginning of our earliest cultures.

Naturopathic physicians believe that the body has a powerful ability to maintain health and repair to a healthy state after disease by virtue of its inherent power of vitality. This homeostatic healing mechanism has been selected by nature in the same way that the organs that we consider to be vital to our survival have been selected. Healing happens unaided by simply maintaining an environment that does not obstruct the path of cure.

Because placebo literature documents the philosophical foundations of the naturopathic health care model, it is important to review the full scope of this subject. Integrating known placebo initiators in clinical practice is essential for good patient care.

WHY STUDY THE PLACEBO EFFECT?

For hundreds of years, physicians have watched their patients respond to therapies with a wide range of results. Some patients recover fully, whereas others, with apparently identical diseases and therapies, wither and die. Today, a skilled physician can correctly diagnose the condition of a patient by applying the sophisticated techniques of modern medicine. Then, an appropriate therapy, the efficacy of which has been thoroughly proven in research and clinical trials, can be prescribed. Through this process the patient will have received the best care available through current medical technology. However, if the diagnosis, therapy, and therapeutic interaction do not stimulate the hope, faith, and belief of the patient, the chances of success are measurably diminished. It has been repeatedly demonstrated in the literature on the placebo effect,[13] psychoneuroimmunology,[5] and psychosomatic,[14] behavioral,[15,16] and psychiatric[17] medicine, that the beliefs of both the patient and the doctor, and their trust in each other and the process, generate a significant portion of the therapeutic results.[18]

The placebo and its effect are not separate from any aspect of the therapeutic interaction, nor are they "nuisance variables" muddying a clear clinical picture. Rather, they send the physician a strong message: it is a patient's own belief system that mobilizes the inherent healing powers of the mind. By studying the placebo effect, a physician is better able to fully harness this power to trigger internal healing mechanisms. Yet, despite the quantity of documentation, the placebo effect remains one of the most misunderstood areas in modern medicine.

The physician should always strive to stimulate self-healing, or the placebo effect, as fully as possible to maximize its potential for healing. Someday physicians will be able to explore the deepest recesses of the unconscious to directly access therapies that assist the body in restoration of internal homeostasis. The optimal model for health care is the marriage of appropriate medical technology with the factors that have been shown to generate the placebo effect. This exciting scenario shines on the horizon as the health care of the future.

Because the doctor–patient relationship is such fertile ground for stimulating the healing response,[19-21] it serves a physician well to comprehend the nature of the placebo phenomenon to fully realize this potential for healing.

HISTORY OF PLACEBO

Both the modern physician and primitive medicine men and shamans of the past used ineffective therapies to stimulate healing in their patients. As Shapiro observed, "the true importance of placebo emerges with a review of the history of medical treatment."[22] It was noted that the historic therapies of the medical profession and traditional healers, "purging, puking, poisoning, puncturing, cutting, cupping, blistering, bleeding, leeching, heating, freezing, sweating, and shocking,"[23] worked because of the placebo effect. Although in retrospect, these practices might seem ludicrous, all of these therapies were once considered effective. As an embarrassing epilogue, placebo literature showed that ineffective procedures are just as pervasive in modern medicine as in the jungle hut of the shaman. We must therefore ask ourselves how unfounded medical therapies can survive peer-reviewed literature and centuries of cultural acceptance.

The power of the patient's belief in the potential for cure has been consistently observed throughout history. Both Galen and Hippocrates recognized the strong effect of the mind on disease and recommended that faith, treatment ritual, and a sound

doctor–patient relationship could provide important therapeutic results.[24] Recognition of the power of positive expectation was recorded frequently in the medical literature of the seventeenth and eighteenth centuries. It was in the eighteenth century that placebo was first defined as a "commonplace method of medicine."[25] As the importance of drug therapy grew in the nineteenth century, the term placebo became identified with medicines involving substances that resembled drugs. However, in the 1940s, because of the increase in double-blind research, it became associated with inert substances that were used to replace active medication.

ORIGIN OF THE TERM PLACEBO

The original Latin meaning of *placebo* is "I shall please."[26] Although the term had a purely medical application in the first half of the twentieth century, its meaning has been subject to various interpretations throughout the last several hundred years.

Before the 1940s, placebos were pharmacologically inactive substances, such as saline and lactose pills, used to satisfy patients that something was being done for them—in other words, the doctor was "pleasing" the patient. The 1940s and 1950s saw an explosion of the use of double-blind experimental procedures to evaluate the growing number of new drugs and medical procedures. Suspicion arose that all medical therapies contained an element of placebo phenomena.[27] This new understanding pressed the scientific community to offer new, far broader definitions.

Shapiro[23] offered the classic definition of a placebo:

> *Any therapeutic procedure (or that component of any therapeutic procedure) which is given deliberately to have an effect, or unknowingly has an effect on a patient, symptom, syndrome, or disease, but which is objectively without specific activity for the condition being treated. The therapeutic procedure may be given with or without the conscious knowledge that the procedure is a placebo, may be an active (non-inert) or inactive (inert) procedure, and includes, therefore, all medical procedures no matter how specific—oral and parenteral medications, topical preparations, inhalants, and mechanical, surgical, and psychotherapeutic procedures. The placebo must be differentiated from the placebo effect which may or may not occur and which may be favorable or unfavorable. The placebo effect is defined as the changes produced by placebos. The placebo is also used to describe an adequate control in research.*

A more accurate definition would be: "Placebo effect is the process of a physician working with the self-healing processes of a patient. Placebo response means healing that results from the patient's own natural survival and homeostatic defense mechanisms."

Modern placebo definitions extend to its nature, properties, and effects. Placebo can be known or unknown, active or inactive, positive or negative in results (placebo effect vs nocebo effect), and can extend to all forms of diagnostic or therapeutic modalities[28] as further defined in Box 6-1.

BOX 6-1 Types of Placebo

Known placebo: Placebo used in a single-blind experiment. The doctor knows it is placebo but the patient does not.

Unknown placebo: Double-blind use of placebo. Neither the doctor nor the patient knows that the medication is a placebo.

Active placebo: Any substance that has an intrinsic physiologic effect that is irrelevant to the ensuing placebo effect. The vasodilating effect of niacin would make it a good active placebo.

Inactive placebo: Any substance that is used with medicinal intent but that has no inherent physiologic effect. Aside from the glucose effect in a sugar pill (or, to complicate things, an allergic reaction to some component of the supposedly inert substance), it has no physiologic effect.

Placebo effect: Any changes that occur in a patient as the result of placebo therapy.

Nocebo effect: Any changes that occur as a result of placebo therapy that are perceived as negative or counterproductive to the path of cure.

CLINICAL OBSERVATIONS OF "KNOWN" PLACEBO THERAPY

One of the more dramatic examples of the placebo effect reported in the medical literature involved a patient with advanced lymphosarcoma, which Klopfer[29] reported was highly susceptible to the patient's faith in an experimental drug called Krebozion. When the patient was started on the drug injections, his enthusiasm was so intense that "The tumor masses had melted like snowballs on a hot stove, and in only a few days, they were half their original size!"[29] The injections were continued until the patient was discharged from the hospital and had regained a full and normal life, a complete reversal of his disease and its grim prognosis.

Within 2 months of this recovery, reports that the drug Krebozion was ineffectual were leaked to the press. Learning of this report, the patient quickly began to revert to his former condition. Suspicious of the patient's relapse, his doctors decided to take advantage of the opportunity to test the dramatic regenerative capabilities of the mind; a single-blind study was performed on the patient using pure placebo. He was told that a new version of Krebozion had been developed that overcame the difficulties described in the press, and some of the drug was promised to him as soon as it could be procured.

With much pomp and ceremony, saline water placebo was injected, increasing the patient's expectations to a fevered pitch. Recovery from his second near terminal state was even more dramatic than the first. Tumor masses melted, chest fluid vanished, he became ambulatory, and even went back to flying again. At this time he was certainly the picture of health. The water injections were continued, since they worked such wonders. He then remained symptom free for over two months. At this time, the final American Medical Association announcement appeared in the press—"nationwide tests show Krebozion to be a worthless drug in the treatment of cancer." Within a few days of this report, the patient was readmitted to the hospital in extremis. His faith was now gone, his last hope vanished, and he succumbed in less than two days.[29]

Other famous placebo case studies are one reported by Cannon[30] on "voodoo death" caused by belief, and one reported by Kirkpatrick,[31] who documented the spontaneous regression of lupus erythematosus resulting, in part, from the patient's belief in the removal of a curse.

Other Clinical Observations

Belief sickens, belief kills, belief heals.[32]

Evans[33] and Beecher[34] reviewed, between them, 26 double-blind studies on the efficacy of active analgesic drugs in the treatment of pain. Independently, they concluded that 35% of patients with pain experienced a 50% reduction in their symptoms after placebo medication. These were particularly remarkable results when viewed in the context of Evans's observation that

BOX 6-2 Symptoms and Side Effects of Placebo Response

- Anger[35]
- Anorexia[36]
- Behavioral changes[37]
- Depression[38]
- Dermatitis medicamentosa[36]
- Diarrhea[36]
- Drowsiness[38]
- Epigastric pain[36]
- Hallucinations[39]
- Headache[40]
- Lightheadedness[36]
- Palpitation[36]
- Pupillary dilation[34]
- Rash[36]
- Weakness[36]

with a standard dose of morphine, only 75% of the patients experienced a 50% reduction in pain. In calculating the efficiency index of placebo analgesia, a method often used to determine the relative efficiency of drugs, placebo was 0.56 as effective as a standard dose of morphine. This prompted Evans to remark, "Thus, on average, placebo is not a third as effective as a standard injection of morphine in reducing severe clinical pain of various kinds but is in fact 56% as effective."[33]

As discussed previously, placebo has been evaluated in a wide variety of clinical settings in addition to pain management (Box 6-2). When a phenomenon such as placebo has been observed to be active in diverse clinical situations, such as surgery, drug therapy, psychotherapy, and biofeedback, and over a range of physical and mental symptoms, the conclusion that it must be a factor in all aspects of medicine is inescapable.

In addition to the variety of positive effects that placebo produces are the *nocebo effects*, perceived as counterproductive to the therapeutic goals. These side effects are frequently consistent with those of the medication that patients believe they are getting. For example, the studies that measure the effects of a supposed aspirin usually show nocebo effects of ulcerlike pain.[41]

In homeopathy, aggravations and ameliorations are commonly seen when a placebo is given to fend off a patient's need to take a medication while the homeopathic physician is waiting to see whether a high-potency remedy will effect a cure. Homeopathic doctors report that placebos can cause anxiety and loneliness as well as calmness and immediate relief from insomnia.[42]

PLACEBO MYTHS

Investigation of the understanding of placebo found in the current medical literature revealed the misconceptions that prevail about the nature of placebo therapy and its effectiveness.[42] A study undertaken to examine doctors' and nurses' attitudes about the efficacy and use of placebos showed that both groups underestimated the number of patients who could be helped by placebo.[43] Physicians showed a consistent pattern of placebo use, as follows:

- Placebos were used to prove the patient wrong through diagnosis of psychogenic symptoms in patients who were thought to be exaggerating, imagining, or faking their symptoms.
- Placebos were used in the treatment of alcoholic, psychotic, and demanding patients who were disliked by the staff of the hospital.
- Placebos were used as treatment in situations in which standard treatments failed or the patient was getting worse.

These misconceptions regarding the nature of the placebo accounted for its widespread misuse in patients who were perceived as uncooperative or who were suspected of malingering.

TABLE 6-1 **Physiologic Changes Induced by Placebo**

PHYSIOLOGIC FUNCTION	PHYSIOLOGIC CHANGES
Heart	Improved exercise tolerance[45,46] Decreased serum lipoproteins[47] Improved T waves[48] Decreased pulse rate and arterial pressure[49]
Sympathetic stimulation	Decreased tremulousness, sweating, and tachycardia[36]
Claudication	Increased walking distance[50]
Opiod dependence	Addictive drug withdrawal[51]
Postsurgical trauma	Decreased facial swelling[52]
Diabetic blood sugar dyscrasias (NIDDM)	Lowered fasting blood sugar[53,54]
Gastrointestinal secretion and motility	Decreased gastric acid secretion[55] Changes in gastric motility[56,57] Healing of duodenal ulcers[58]
Hypertension	Lowered blood pressure[59-61] Reduced urinary catecholamines[62]
Motor dysfunction	Improved tremor magnitude[63]

NIDDM, non–insulin-dependent diabetes mellitus.

Myths about placebos continue to hinder full understanding about the power inherent in this aspect of health care. The most common myths are discussed here.[44]

Myth 1

"Since placebos tend to be physiologically inert, it is not possible for them to have an effect on physiologic homeostasis."

Fact. Research showed that placebos have a wide range of effects (Table 6-1) that are found throughout all aspects of human physiology.

Myth 2

"Placebos are useful only with symptoms that are associated with psychological or psychosomatic complaints. Patients who need a placebo are hypochondriacs with vivid imaginations and need to be palliated with something 'to please them'."

Fact. Placebos have been shown to be effective in the care of all types of patients, with a consistent level of positive results for a wide variety of accurately diagnosed diseases.

Beecher[18] was one of the first to compile a listing of the therapeutic effectiveness of placebo, thereby uncovering the wide range of therapeutic applications that were previously thought to be limited to only pain control. He concluded, "there is too little scientific as well as clinical appreciation of how important unawareness of these placebo effects can be and how devastating to experimental studies as well as to sound clinical judgement lack of attention to them can be."[18]

The large and ever-growing number of studies on placebo and double-blind research (Box 6-3) supports the following assertion made by Beecher[18] 30 years ago:

> *Many "effective" drugs have power only a little greater than that of placebo. To separate out even fairly great true effects above those of placebo is manifestly difficult to impossible on the basis of clinical*

BOX 6-3 Conditions That Have Been Shown to Respond to Placebo

- Angina[45,46,64-66]
- Anxiety[36,67,68]
- Arthritis[41,69,70]
- Asthma[71-74]
- Behavioral problems[75]
- Claudication, intermittent[50]
- Common cold[76-79]
- Cough[80]
- Depression[81,82]
- Diabetes (non–insulin-dependent diabetes mellitus)[53,54]
- Drug dependence[36]
- Dysmenorrhea[83]
- Dyspepsia[84]
- Gastric ulcers[85]
- Hayfever[86,87]
- Temporal and vascular headaches[88-90]
- Hypertension[91,92]
- Labor and postpartum pain[93]
- Premenstrual syndrome[94]
- Ménière's disease[95]
- Nausea of pregnancy[36]
- Pain[96,97]
- Psychoneuroses[98,99]
- Rhinitis[100]
- Sleep disturbances[101]
- Tremor[64]

impression. Many a drug has been extolled on the basis of clinical impression when the only power it had was that of a placebo.

Myth 3

"The placebo effect is found only in substances that are inert."

Fact. Placebo phenomena have been observed across a wide spectrum of medical disciplines, including surgery,[102] drug therapy,[103] and biofeedback.[104]

Myth 4

"The patient who responds to placebo can be characterized as someone who is of a typical neurotic disposition."[43]

Fact. Although many studies have tried to impute a personality type, disposition,[104,105] or certain epidemiologic class[106] to the patient who responds to placebo, this has yet to be well demonstrated, because given the right circumstances, any person can become a placebo reactor.[107,108]

After reviewing the bulk of the research on this subject, Bush[109] and Wolf and Pinsky[36] concluded that the attempts to pigeonhole personalities into a clinical profile ignored the complexity of the human mind. Gliedman et al[98] similarly reported that age, sex, marital status, social class, and intelligence were unimportant factors in determining a patient's response to placebo. Wolf summarized that attempts to identify placebo reactors need to

> *"identify the nature of the symptom being treated, the motivation of the patient and physician, the nature of the test agent, its mode of administration and the life situation of the subject at the time he is tested. The significant point here is not the apparently conflicting findings of investigators with respect to placebo reactors, but rather that in any given situation, responses to a placebo may vary as compared to any other situation and the significance of situations to human subjects cannot be precisely duplicated."*[36]

PHARMACODYNAMICS

The physiologic response of the "inert and inactive" placebo extends into the realm of drug pharmacodynamics. Dose–response time curves, cumulative effects (increasing therapeutic efficacy with repeated doses),[110] variable strengths of analgesia based on a patient's drug expectation,[64] drug interactions,[36,111] and carryover effects[39,105] have all been demonstrated. The effects of placebo are so pronounced that some observers have suggested that they can exceed the effects attributable to potent pharmacologic agents.[36]

Packaging and Delivery

Several studies found that the effectiveness of placebo therapy depends on the mode of delivery.[48] For example, one study found that green tablets improved anxiety and yellow tablets improved depression,[112] whereas another study found that blue capsules were more sedative and pink capsules were more stimulating.[49] Placebo injections appeared to be more effective than oral administration after oral placebo failed to relieve the symptoms.[41]

Placebo Interactions

Benson[113] wrote that the patient's belief was also a powerful force in determining the level of relief afforded by the placebo. An increase in patient expectation enhances the physician's ability to elicit a placebo response. Even if patients know that they are receiving placebos, the expectation and relief brought about by the therapeutic interaction provides positive results.[114] The importance of expectation was further demonstrated by the observation that the greater the stress level of the patient and the greater his or her need for assistance, the greater the effectiveness of placebo.[38] This was seen even in patient responses to psychotropic drugs: D-lysergic acid diethylamide tartrate 25 (LSD-25) could have no effect if the patient was told that the drug was a placebo.[104,115]

Patients, such as war heroes, who had severe injuries but did not have great mental suffering attached to their pain needed less pain medication than persons with similar injuries who had pain that engendered anxiety and connoted disaster.[116]

PLACEBO HEALING MECHANISMS

When animals or humans can react to their own deviations from homeostasis and when these deviations set off restorative processes, therapeutic intervention, including placebo, has an already existing substrate of recovery for exploitation.[15]

A human being has an intrinsic ability to "self-right"—*vis medicatrix naturae* (the healing power of nature). This is the keystone of a philosophy that has been held for thousands of years by naturally oriented physicians (see Chapter 5). The concept of a homeostatic, self-regulating mechanism is central to the understanding of basic concepts of physiology: negative feedback loops control virtually all systems of the body. According to Guyton,[117] "the body is actually a social order of about 75 trillion cells organized into different functional structures.… [E]ach cell benefits from homeostasis and in turn each cell contributes its share toward the maintenance of homeostasis."

The body can maintain health and reestablish a healthy state after disease by virtue of its inherent vitality. This is part of the definition of a homeostatic mechanism; it has been selected by nature in the same way that organs vital to our survival have been selected. The surviving species are those most fitted and best able to cope with dysfunction. Those organisms that can tolerate the greatest stresses and still maintain a normal physiology are the hardiest survivors and ensure the species' ability to increase the limits of its adaptation. Therefore, given that an organism is self-maintaining when in an environment that it has been selected for, healing happens unaided through simply maintaining an environment that does not obstruct the path of cure. As Norman

Cousins[118] observed, "without any help, the human body is able to prescribe for itself. It does so because of a healing system that is no less real than the circulatory system, the digestive system, the nervous system, or any of the other systems that define human beings and enable them to function."

The Role of Emotions

Starting in the 1970s and early 1980s, review articles began to examine the effect of the mind on the immune system, emphasizing mechanisms and pathways that gave rise to a new field called psychneuroimmunology.[4] Reviews of studies that explored how specific emotions can increase cancer susceptibility,[119,120] examined the effect of emotions and recovery from cancer,[121] investigated the increased incidence of sudden and rapid death during psychological stress,[122] and monitored the changes in immune function during emotional stress[123,124] all confirmed that emotions play a powerful role in the prognosis of a patient. Cannon[30] and Tregear[125] documented dramatic case histories of pioneering anthropologists who witnessed the power of taboos and curses to kill strong healthy men and women in third world cultures throughout Africa, South America, and the South Pacific. Tregear[125] wrote, "I have seen a strong young man die the same day he was tauped [tabooed]; the victims die under it as though their strength ran out as water."

The *Vis Medicatrix Naturae*

The healing process described as *vis medicatrix naturae* demonstrates the significant power and potential of the self-generated healing capacity. For a physician, there is no more powerful stimulator of this healing mechanism, the placebo effect, than a strong doctor–patient interaction. Just walking through the door of the physician's office nudges a patient's internal homeostatic mechanisms into seeking higher levels of health, healing, and adaptation. The placebo effect is a result or effect of the patient's seeking the assistance of the doctor's ability to heal and cure. As Benson[113] noted:

> *When we dissected the placebo effect a number of years ago, we found three basic components: One, the belief and expectation of the patient; two, the belief and expectation of the physician; and three, the interaction between the physician and the patient. When these are in concert, the placebo effect is operative.… Perhaps nothing is being transmitted from the healer to the patient, but rather it's the belief the patient has in the healer that's helpful.*

Conscious Control Over Homeostasis

The body has two internal forces to maintain homeostasis: a lower drive and a higher drive. The lower drive is the inherent internal healing mechanism, the vital force, or the primitive life support and repair mechanism that can operate even in a person who is asleep, unconscious, or comatose. The higher drive is the power of the mind and emotions to intervene and affect the course of health and disease by depressing or stimulating the internal healing capacities. The effect of this drive can be seen in the clinical observation of patients who move toward spontaneous remission of a life-threatening disease through positive emotional support[13,121] and in patients who fail to express emotions compatible with the body's attempts to survive.[121]

In any disease process, the consciousness of the patient decides the effectiveness of any therapy. It has been suggested that a wide range of nondrug stimuli has the capacity to modulate human functioning.[126] It is emerging in medical literature that any sensor stimuli or mental activity is able to alter disease progression. This extends to the thoughts and intentions of those connected to the patient. Experiments in remote intention-generated healing and prayer showed that the intention of others was a factor in the homeostatic capabilities of the mind and body. The fact that the homeostatic mechanism can sense and respond to these remote intentions is a reflection of the power of the human mind. Some authors believe that there is a physiologic basis for the unlimited possibility of human voluntary control.[127] The conclusion that awareness or "mind," anyone's mind—the patient, the doctor, or someone who is aware of the patient—can alter the patient's physiology is testament to the "holos" concept in different schools of alternative and complementary medicine. This idea flies so deeply in the face of our mechanistic model of medicine, it forces a complete paradigm shift in the conventional social ethos of medical care.

The ultimate control of psyche over soma demonstrates the priority of the conscious mind over physiologic processes such as immunity and pain control.[128] This puts an enormous responsibility on the physician. He or she must take full account of a patient's mental and emotional states when treating chronic or life-threatening disease.

Physiologic Mechanisms

Identification of a biochemical mechanism for placebo analgesia has done more to change the image of placebo than any amount of arguing about the importance of beliefs and the mind.[129]

The mechanisms of placebo response have been suggested to be a mixture of psychological interactions mediating physiologic responses.[17] Psychological components of the patient's placebo effect have been shown to include decreased anxiety and increased relaxation,[64] conditioning,[16] expectation,[21] and well-being generated by the establishment of a sound doctor–patient relationship.[130,131]

Review articles summarized a wide range of receptor agonist mechanisms driving the neural pathways in different parts of the brain.[132] To date, endorphin, dopamine, cholecystokinin, interleukins, growth hormone, and cortisol have been implicated. The physiologic mechanisms of the placebo effect were suggested to include chemicals, catalysts, and enzymes. It is believed that steroids, catecholamines,[13] the autonomic nervous system,[17,133] neuropeptides, and endorphins[134] are also involved. These physiologic mechanisms interrelate synergistically and are rapidly being researched within the rapidly developing field of psychoneuroimmunology,[6] through which the links between depression, affective disorders, emotions, and the immune system and central nervous system (CNS) are being explored. Susceptibility to depression and sensitivity to pain have now been found to be mediated through neurotransmitters such as catecholamines, serotonin, and dopamine.

The current model for explaining the mechanism by which emotions, mood, and psychological stress suppress immune function involves cerebral–hypothalamic and pituitary interaction, which translates stress and anxiety into an autonomic–endocrine response. This response adversely affects the immune function, particularly after chronic stimulation. Stressful stimulation is received in the sensory cortex of the brain and is then referred to the limbic system and the hypothalamus. This interface of higher brain functions and homeostatic regulating centers provides the communication link between the psyche and soma. According to Rossi,[17] "The hypothalamus is thus the major output pathway of the limbic system. It integrates the sensory-perceptual, emotional, and cognitive function of the mind with the biology of the body."

The nerve centers that control both branches of the autonomic nervous system (both parasympathetic and sympathetic), nerve cells that secrete endocrine-releasing factors, and neural pathways that release hormones directly into the posterior pituitary are in the hypothalamus. The corticosteroids and catecholamines from sympathetic stimulation are key factors in the alteration of disease susceptibility in response to stress. Corticosteroids inhibit the function of both macrophages and lymphocytes, as well as lymphocyte proliferation.[135] Corticosteroids also cause the thymic and lymphoid atrophy noted by Hans Selye in his experiments on stress-induced immune dysfunction.[136]

The autonomic release of catecholamines stimulates receptors on the surface of lymphocytes, thereby increasing their maturation rate. When lymphocytes are in a mature state, their ability to kill bacteria and cancer cells and produce interferon seems to become paralyzed.[137] Thus a population of mature lymphocytes develops, ready to defend the body from infection and inflammation, yet remains paralyzed until the "red alert" signal of sympathetic fight or flight is turned off, signaling the appropriate time to rest and repair.

A number of other peptides, E-type prostaglandins, somatotropin, histamine, insulin, endorphins, antidiuretic hormone, and parathyroid hormone all have receptor sites on lymphocytes and can stimulate the same cyclic adenosine monophosphate mediated response resulting in lymphocyte maturation and inhibition.[135] A study of the effect of catecholamines on the human immune system showed that when a physiologic dose of epinephrine was injected into a healthy volunteer, there was an increase in the number of circulating suppressor T lymphocytes and a decrease in the number of circulating helper T lymphocytes (changes similar to those found in acquired immunodeficiency syndrome [AIDS]).[135]

Neurophysiology of Placebo Response

Medical research has continued to expand the understanding of placebo healing response, expanding the understanding of the complexity of the brain functions that control healing in the body.[138] One review article did an excellent job of summarizing the psychobiological mechanisms involved in the wide array of medical conditions observed in placebo response literature.[1] Imaging techniques such as positron emission tomography and functional magnetic resonance imaging (MRI) have literally illuminated the areas of the brain involved in generating placebo.[139] One fascinating development is the indication that the placebo effect may be especially useful in depression, anxiety, substance abuse, and neurodegenerative diseases like Parkinson's disease and Alzheimer's disease. Research has indicated that conditioning and anticipation of the patient has a potent effect of stimulating specific brain region activity associated with pain modulation and neurohormonal regulation.

Brain Region Activity

Some of the most interesting research on placebo has evolved out of the new MRI technology. This functional MRI (fMRI) can measure blood flow into specific areas of the brain. One study showed that expectation or hope was able to stimulate a certain part of the brain that is activated by pain medications and is associated with pain relief. Placebo analgesia was found to be related to decreased brain activity in pain-sensitive brain regions, including the thalamus, insula, and anterior cingulate cortex. It was also associated with increased activity during anticipation of pain in the prefrontal cortex, providing evidence that placebos alter the experience of pain.[140]

In another study, researchers found that empathy could activate a portion of the brain. They showed that some of the brain regions involved in feeling physical pain became activated when someone empathized with another's pain. Using fMRI, study participants were observed when they experienced a painful stimulus, and the results were compared with those elicited when the participants observed their spouses receiving a similar pain stimulus. The bilateral anterior insula, rostral anterior cingulate cortex, brainstem, and cerebellum were activated when participants received pain and also by a signal that a loved one experienced pain.[141] A group of researchers at University of California at Los Angeles, using a new technology called quantitative electroencephalography, showed that "effective" placebo treatment induced changes in brain function that were different from those associated with antidepressant medication. Placebo responders (those who showed a response to placebo) showed a significant increase in prefrontal activity starting early in treatment that was not seen in medication responders or in participants who showed no response to medication or placebo. Because a high percentage of antidepressant medication represents the placebo effect, it is important to be able to predict who will be placebo responders.[142]

Placebo and Stress Physiology

Stress "letdown" of a patient in the therapeutic environment is one of the mechanisms that produces the placebo effect. It results from the patient's perception that a transition from a stressful situation to a nonstressful situation has occurred. Mowrer[137] observed that with a decrease in anxiety there is a concomitant increase in hope, signifying that the period of suffering is over. Certain familiar images and signals, such as white coats, syringes, behavioral procedures, and clinical protocol, create a conditioned response—relief now that help has arrived. Evans and Hoyle[64] similarly observed that "the reduction of fear through the shared expectations that the doctor's medicine will work—even if unknown to the patient it is placebo—mediates powerful therapeutic effects."

The placebo effect in the clinical environment transforms the emotional and mental stress of the patient. These effects, also observed and described by Franz Alexander,[14] Hans Selye,[136] George Solomon,[143] and Walter Cannon,[144] allow the patient to escape the "fight or flight" response that can cause and maintain the state of illness.

Physiologic and Psychological Stress

Selye[136] demonstrated that physiologic stress can have a dramatic effect on the immune and endocrine systems of the body. Laudenslager[145] went on to show that it is not just stress that creates these physiologic changes, but also the perception that stress is "inescapable" that is critical to the response. More recently, studies on the effects of psychological stress demonstrated significant changes in immune capability. Maladjustment to "life-change stress" correlated with reduced activity of natural killer cells,[143] decreased T- and B-cell responsivity,[123] and diminished lymphocyte cytotoxicity.[146] For example, Riley[147] observed increased tumor activity in a controlled stress environment and concluded:

> *Emotional, psychosocial, or anxiety-stimulated stress produces increased plasma concentrations of adrenaline, corticosteroids and other hormones through well-known neuroendocrine pathways. A direct consequence of these increased corticoid concentrations is the injury to elements of the immunologic apparatus, which may leave the subject vulnerable to the action of the latent*

oncogenic viruses, newly transformed cancer cells, or other incipient pathologic processes that are normally held in check by an intact immune system.

The damage to the immune system by stress, mediated through the hypothalamic–pituitary axis, has been shown to be due to the increase in serum levels of cortisol. In one study, elderly caregivers were shown to have higher cortisol levels and poor antibody response to influenza vaccine.[148] The impact of cortisol on immune and other regulatory functions like blood sugar, dehydroepiandrosterone (DHEA), insulin, testosterone, and bone resorption, flag it as having highly destructive potential. Anxiety, depression, heart disease, AIDS, and osteoporosis have all been linked with elevated cortisol levels. DHEA, another adrenal hormone, is also modulated by stress physiology, although it seems to have the opposite effect to cortisol. High levels of DHEA seem to protect the body from the damaging effects of elevated cortisol. Ratios of DHEA to cortisol are highly predictive of the individual's ability to tolerate stress.[149]

Current reviews of the literature relating psychological stress and immune dysfunction support the hypothesis that homeostatic immune mechanisms, both humoral and cellular, are significantly impaired by both natural and experimental stress.[4,114,134,150] Hypertension,[151] common colds,[152] coronary artery disease,[153] and myocardial ischemia[154] were linked to adverse stress physiology. Stress even has the ability to increase permeability of the blood–brain barrier.[155] The implications of stress-related alterations in the blood–brain barrier exposes important insights into enigmatic diseases like chronic fatigue syndrome and stress-induced neurologic disorders.

Endorphins, Hormones, and Neuropeptides

… one rapidly activated psychoneuroendocrine mechanism through which a placebo stimulus may reduce both depression and pain is produced by stimulating the endorphin system.[16]

Research on endorphins is a relatively new area of study in the field of psychoneuroimmunology. Original research by Levine et al[96] suggested that the pain relief noted in placebo studies could be explained by the simple mechanism of endorphin-mediated actions. The original emphasis on endorphins and enkephalins was plausible, considering their known modulation of pain and mood functions. This position was further supported by later observations that depression increased chronic clinical pain[156] and that decreased activity in endogenous opioids may be part of the pathophysiology of depression.[157] With the information that placebo can stimulate endorphins, Levine et al[96] believed that an explanation for the action of placebos had finally been found. Furthermore, research showed that a endorphin-mediated, pain-suppressant placebo effect could be abolished with the use of Nalaxone, an opiod antagonist.[158] The same authors went on to further show that endorphin-mediated placebo effects penetrated other physiologic systems besides pain management.[159] However, this hypothesis failed to account for the broad spectrum of placebo effects as well as for the fact that the analgesia associated with hypnosis was not affected by an opioid antagonist.[160,161] It is important to note that later literature suggested that Levine et al[96] were not entirely wrong in implicating the role of endorphins in the placebo mechanism; rather, these researchers were right for the wrong reason.

Endorphins are mainly derived from three precursor proteins (by separate biochemical processes).[162] These opioid peptides are released from central and peripheral areas in response to pain, stress, and emotions and perform many physiologic functions, of which analgesia is but one.[163] However, it is becoming evident that the boundaries between the CNS and the immune system are not as clear as once thought. The several known effects of endorphins on immune system function are listed in Table 6-2.[164]

TABLE 6-2 **Effects of Endorphins on the Immune System**

IMMUNE SYSTEM FUNCTION	ENDORPHIN EFFECT(S)
Lymphocyte production	Increased and decreased
Chemotaxis	Increased
T-cell sensitivity to prostaglandin E_2	Increased
Antibody production	Increased and decreased
Complement	Binding of fractions C5B-C9
T-cell proliferation	Modulation of
Natural killer cell function	Modulation of
B-cell differentiation	Modulation of

When the functions of neurotransmitters such as endorphins are found to have such an intimate relationship with immune integrity, the paradigm of a body with functions performed independently by its parts—a Newtonian type of thinking—begins to lose credibility. To further blur the already hazy distinction between the CNS and the immune system, research demonstrated that endorphins and peptide hormones, such as adrenocorticotropic hormone, thyroid-stimulating hormone, human chorionic gonadotropin, and luteinizing hormone, are produced by lymphocytes.[164]

It is clear that the demarcation between the CNS and the immune system is impossible to distinguish. The brain and the immune system are the only tissues in the body that have a memory, and the level of communication between the two argues a taxonomy that identifies them as one. Evidence of the innervation of the thymus gland, bone marrow, spleen, and lymph nodes supports the finding that the immune system is subject to efferent CNS information.[164] In addition, studies demonstrating the atrophy of the thymus and lymphatic tissues in the absence of growth hormone,[165] adrenocorticotropic hormone, and increased steroid production by adrenal cells after interferon stimulation, indicate that "in the future it will be difficult to distinguish the receptors and signals that are used within and between the neuroendocrine and immune system."[164]

CLINICAL APPLICATION

Whether a clinician intends to initiate a placebo effect in a clinical setting or not, the mind of the patient will initiate some subliminal healing effects according to their hope, expectation, conditioning, anxiety reduction, and meaning around the disease and treatment. A recent article in *Lancet*[1] on placebo concluded, "Any ethical assessment of efforts to promote placebo effects in clinical practice first requires knowledge as to the clinical relevance and importance of placebo effects."

A physician with an interest in psychopharmacologic treatment, which can be expensive, elaborate, detailed, time consuming, esoteric, and dangerous, usually has considerable knowledge about such treatment. He or she is interested in the symptoms of the patient and the differential response to various drugs and is careful to observe side effects, which may be dangerous. The physician may encourage the patient to call at any time if side effects develop.[24]

BOX 6-4 Six Principles of Optimizing Placebo Response in Clinical Practice

Prima non nocerum: Prioritize a hierarchy of therapeutic intervention.
Tollem causum: Remove the obstacles.
Support the therapeutic relationship.
Enhance positive emotional states.
Implement therapeutic conditioning or learning.
Use altered states of consciousness.

The application of placebo phenomena in clinical practice should not be a vague attempt to replace the skill of the medically trained physician with obscure "hand waving," incantations, and inert lactose pills. In primary care and specialty clinical practice, the physician's intent should be to optimize patient care by engaging restorative defense mechanisms. To effectively apply current placebo research, the physician must understand several principles (listed in Box 6-4 and discussed here).

Prima Non Nocerum: Prioritize a Treatment Program and Establish a Hierarchy of Care

Prima non nocerum is the Hippocratic injunction dictating that a physician care for the patient so that self-healing mechanisms can engage. This ancient phrase means "Do not disturb the organism's ability to heal itself." The body must be given the full range of possibilities in allowing the power of homeostasis, *vis medicatrix naturae*, to have its optimum capability. "Doing no harm" means that a patient is supplied with the level of medical intervention that is appropriate to his or her ability to maintain life support. The job of the physician is to determine when homeostasis or the defense mechanism has lost the ability to respond to disease.

Acute traumatic swelling and inflammation and shock are examples of the human defense mechanism responding in a way that threatens the health of the organism. It is most interesting that the organism would make choices, as in shock and inflammation, that could kill it. To practice the principle of *prima non nocerum,* a physician must learn when to act and when to let the body heal itself. This is the highest art of medicine; each case and situation is different and it is up to the physician to interpret the needs of the moment. By implication, the physician who seeks to apply this principle understands the principles of physiology upon which human life depends for homeostasis.

Prima non nocerum does not necessarily mean that a physician withholds invasive therapy: it is the physician's responsibility to determine when the body is unable to reestablish homeostasis and therapy is indicated. If an arm must be severed to save the patient's life, there is no violation of *prima non nocerum*.

However, to enhance the principle of *prima non nocerum*, a physician sometimes must withhold therapies and must be content to leave the patient to self-heal. Hippocrates understood the wisdom of letting the body heal on its own, which is implicit in the "do no harm" injunction. The following account of the treatment of Charles II of England is a case in point[166]:

> *A pint of blood was extracted from his right arm and a half pint from his left shoulder, followed by an emetic, two physics, and an enema comprised of fifteen substances; the royal head was shaved and a blister raised; then sneezing powder, more emetics, and bleeding, soothing potions, a plaster of pitch and pigeon dung on his feet, poisons containing ten different substances, chiefly herbs, finally forty drops of extract of human skull and an application of bezoar stone; after which his majesty died.*

When this treatment is compared with modern procedures, such as mammary artery ligation for the relief of angina—a procedure that has no more benefit than sham artery ligation—it appears that physicians continued throughout the centuries to rely on the placebo effect for the care and cure of their patients. Because this effect plays such an important role in health care, simple, noninvasive, and effective treatments should be the goal of all therapeutic approaches. Robert Burton[167] wrote in 1628, "an empiric oftentimes, and a silly chirurgeon, doth more strange cures than a rational physician… because the patient puts confidence in him."

The rational physician will also recognize that healing and curing are not necessarily the same. If a patient is helped in any way by the doctor, with or without the use of placebo, the path of cure has been assisted, although the specific disease may not have responded. Not all patients can be cured, but most patients can be helped.

Tollem Causum: Remove the Cause of Disease

Tollem causum is the principle that seeks to remove the obstacles to cure. The forces "inhibiting the floodgates of health from opening" must be removed for the full force of the patient's beliefs to effect the path of cure. This concept is fundamental to the philosophy of naturopathic medicine with its strong emphasis on diet, detoxification, and a pattern of living that is consistent and compatible with the context in which humans evolved. Obstacles to cure block the self-healing capacity of the organism. Contamination with heavy metals and xenobiotics (see Chapter 35), focal infections, electromagnetic pollution, scar tissue, genetic metabolic abnormalities, and parenchymal organ damage defeat the best therapeutic intentions and must be addressed.

The patient's habitat is an important aspect of the therapeutic protocol, not only in the diagnosis and care of internal mental and physiologic dysfunction, but also in determining which environmental factors may be contributing to dysfunction and disease. These factors might include diet, lifestyle, and living environment. It is of the utmost importance to remove a patient from surroundings that are associated with illness or to assist the patient in creating an environment more conducive to health.

Factors that provide conditioning that reinforces the disease process can be associated directly or indirectly with one's environment. For example, if animals are returned to situations where their experimental neuroses were induced, their pathologic behavior reactivates.[168] When a patient leaves the offending environment to receive treatment from a physician, the prognosis is correspondingly more favorable.[15] The physician has the added advantage of a patient's heightened expectation during an office visit; a patient's positive associations with the "healing" environment increases his or her receptivity to treatment.[169] If the home or work environment is a source of "disease" and an obstacle to cure, providing an alternative environment may be a most helpful way to remove the obstacles to cure.

Support the Therapeutic Relationship

Confidence should surround all aspects of the therapeutic interaction. The patient must have confidence in the doctor's ability to assist a cure, the doctor must have confidence in the efficacy of his or her therapy,[170] and there must be an understanding or

relationship between the doctor and patient that is mutually conducive to respect, trust, and compassion.

The quality of the doctor–patient relationship is paramount. The therapeutic approach to a patient that optimizes the confidence of the patient in the skill of the doctor stimulates the inherent self-regulating healing mechanisms by relaxing the anxiety the patient has about the illness. Anxiety is a well-known immunosuppressant and aggravates the body's defense mechanism. An optimum therapeutic relationship, when combined with the clinical skill to remove the cause of homeostatic dysfunction, is the height of therapeutic acumen. As Lewith[171] so accurately stated, "The general practitioner may therefore wish to employ all his knowledge, enthusiasm, consultation technique and sympathy, to create the best possible atmosphere in which to elicit a placebo response from the patient."

Current research on factors contributing to the genesis of the placebo effect consistently document the importance of the doctor–patient relationship.[172-174] The healing power of the therapeutic interaction has been demonstrated by the commencement of the placebo effect even before the actual administration of the pill.[175]

The physician facilitates the cultivation of a sound relationship by developing good communication skills. The art of the bedside manner has been recognized throughout history as the primary skill a successful physician needs.[176] The history of medicine is as much a history of the relationship between doctor and patient as the evolution of medical technology and techniques. Through centuries in which doctors were doing more harm than good, little more than the esteem of their clientele sustained the medical profession. But however little real help the doctor had to offer, it was to him that people turned when illness struck.[177]

Bedside manner has been found in clinical studies to entirely alter the course of double-blind studies, and the quality of a therapeutic encounter has been found to facilitate or disrupt the efficacy of a treatment.[178] Listening to the patient,[178] verbal and nonverbal communication of the physician, amount of time spent with the patient,[179] patient education,[180] demeanor of the physician,[181] and interview skills[179] have been suggested as factors and components of effective physician communication skills.

Touch is an important form of communication and is sometimes forgotten as a key aspect of the doctor–patient relationship. Highly skilled clinicians with many years of experience, such as now deceased Dr. John Bastyr (whose remarkable healing abilities inspired the founding of Bastyr University by those privileged to have been his students), frequently impressed upon clinicians the importance of always using diagnostic and therapeutic touch during a patient visit. The doctor's touch can be diagnostic, therapeutic, and, perhaps most important, a means of communicating that he or she is deeply attuned to the problems, needs, and fears of the patient.[181] Touch can heal by increasing tissue mobility and fluid exchange, as in massage, or by relieving pain, as demonstrated by research on healers who use their hands.[183] Touch has also been documented in well-designed double-blind research to extend an unusual healing power that can be transmitted through the hands to plants and animals.[184]

Among other methods of enhancing confidence between the doctor and patient, the setting in which a doctor provides therapy to a patient also determines its effectiveness. The doctor's office setting is very important for optimum and effective treatment: tools and support systems are more accessible, and a heightened patient response results from seeking out the "healing" environment. In a clinical trial with hypertensive patients, placebo alone was not as effective as when it was administered in conjunction with hospitalization. The visit to the physician represents a search for changes that cannot be found through "self-care" or over-the-counter medicines. According to Frank[185]:

> *In short, it appeared that the placebo situation relieved chiefly anxiety and depression, that the degree of relief was unrelated to personality and autonomic measures, and that the patients who responded strongly to a placebo at one time might not at another. In conjunction, these results suggest that the extent of responsiveness to a placebo depends on the interaction of the patient's state at a particular time with certain properties of the situation. The finding that administration of tests and questionnaires seemed to have at least as beneficial an effect as had the pill implies that any interaction between patient and situation that heightens expectations of help may lead to symptom reduction and improvement in mood. The aspects of the situation producing this effect include not only presentation of a symbol of the physician's healing powers (a pill), but any attention and interest shown by professional personnel.*

This phenomenon was also observed in industry and termed the "Hawthorne effect." As a direct result of the greater attention factory workers received during investigation, the quality of their work improved.[186] In conclusion, the importance of a doctor–patient relationship and the confidence that it engenders shows that all human beings need to share their feelings and experience the therapeutic benefits of touch: the doctor–patient relationship provides an ideal way to meet these fundamental needs.

Enhance Positive Emotional States

> *Love in all its subtleties is nothing more, and nothing less, than … the psychical convergence of the universe upon itself.*
> ***—Pierre Teilhard de Chardin, The Phenomenon of Man***

For optimum enhancement of the psychoneuroimmune system, the physician must assist the patient in developing practices that amplify positive emotional states and reduce a negative emotional state. A negative mental state (anxiety, stress, panic, anger, depression, neurotic behavior, self-deprecation, self-destructive feelings and tendencies, and a weak will to live) hinders the ideal functioning of the psychoneuroimmune endocrine axis, disrupting homeostasis. Engle[187] termed this the *giving-up/given-up complex*:

> *Study of the life settings in which patients fall ill reveals that illness is commonly preceded by a period of psychological disturbance, during which the individual feels unable to cope. This has been designated the giving-up/given-up complex and has the following five characteristics: a feeling of giving up, experienced as helplessness or hopelessness; a depreciated image of the self; a sense of loss of gratification from relationships or roles in life; a feeling of disruption of the sense of continuity between past, present, and future; and a reactivation of earlier periods of giving-up. It is proposed that this state reflects the temporary failure of the mental coping mechanisms with a consequent activation of neurally regulated biologic emergency patterns. Changes in body economy so evoked may alter the organism's capability to deal with concurrent pathogenic processes, permitting disease to develop.*

The importance of reducing negative mental states in acute and chronic conditions has been discussed extensively.[122] Acute psychological stress is documented to cause various forms of cardiopulmonary dysfunction and even death.[114]

Chronic mental and emotional strain causes breakdown of the immune system and disease. The homeostatic processes become

overwhelmed by autoimmune, microbial, or neoplastic invasion. Major writers on the subject of acute and chronic stress emphasized the high priority of managing the physiologically and immunologically destructive effects of the human body's response to stress. Pelletier[188] listed hypertension, arteriosclerosis, migraine headache, cancer, chronic bronchitis, emphysema, asthma, and arthritis as disease processes that are caused or exacerbated by stress physiology. A study researching the relationship between resistance to streptococcal infections in families and stress load in the family found a positive correlation.[189] Another study on the psychosomatic susceptibility to infectious mononucleosis found that two psychosocial factors, high motivation and poor academic performance, significantly increased the risk of "disease" infection.[190] In still another, anticipation of mood and menstrual discomfort were positively correlated and manipulated, thereby supporting the suspicion that expectations act as a determinant of mood.[191]

The conclusion that there is no acute, chronic, or degenerative disease that is not affected by a patient's mental and emotional state must be drawn from the pervasive immunoendocrine effects generated by the mind and emotions. Wolf[192] and Cousins[193] wrote of the power of panic as a factor in myocardial infarction, Marbach et al[156] described depression as a component in myofascial pain dysfunction, and Shekelle et al[194] noted, in a 17-year follow-up study, a twofold increase in the incidence of cancer in depressed patients. The clinical scenarios these observers described imply that the placebo effect can control the onset and advance of a disease by shutting down the destructive thoughts, images, and feelings that mediate stress.

Enhancing positive emotions is the corollary to controlling the damaging effects of negative mental and emotional states. Laughter,[21] hope,[195] acceptance,[116] and the reduction of suffering[196] have been shown to speed the course of healing and reduce the level of pain and distress reported by patients. Although pain is sometimes the only language nature can use to adequately communicate to the patient that something is in need of healing, "the relief of suffering and the cure of disease must be seen as twin obligations of a medical profession that is truly dedicated to the sick."[196]

Acceptance has been observed to be a key factor that assists patients in better understanding their pain.[116] Acceptance does not mean complacency in the face of disease, but a rational understanding of the situation and the limitations that can sometimes accompany a disease process.

The importance of cultivating hope in a patient also cannot be underestimated.[197] The fact that a patient seeks the help of a physician or "caregiver" already implies a substrate of hope and is a signal that the patient can visualize the potential for recovery. The treatment needs to merely stimulate this willingness to envision a future of health. Hope is an embodiment of the patient's and the doctor's ability to visualize an image of healing and recovery. This process is a recurrent theme in imagery therapy,[198] visualization therapy,[199] therapeutic touch,[200] and psychic healing.[201] Hope is both an active and a passive placebo. *Passive hope placebo* is that which brought with the patient as the act of seeking help generates a level of unspoken faith in an image or potential for cure. *Active hope placebo* is generated by the physician, who consciously instills a vision or image of cure in the patient as an adjunct to therapy.

Frank[185] performed a double-blind study in which patients were divided into control and induction groups. The induction group was led through a process whereby their hope was strengthened to conform with the expectations of the therapist[185]:

> *It introduces some perceptual clarity into the process of treatment; and to the extent that all our therapists adhered roughly to the insight model of therapy, it helped to bring the patient's expectations in line with what actually occurred in treatment, and also helped him behave in accordance with the therapist's expectations of a good patient.*

The induction group was actually being consciously strengthened to a level of optimal response but was not being led into false expectations.[202]

This type of patient education or active placebo is a necessary and useful tool for framing and directing a positive outlook and prognosis. If a patient can conceive of a state of wellness, then that state of wellness can be achieved. It is the job and domain of the physician to discover those images, emotions, and perceptions that reside in the conscious and subconscious mind of the patient that block the image of a positive state of health. He or she must actively work to control these with the same level of intent as with any presenting gross complaint or physiologic dysfunction. Finding these dysfunctional mental substrates and working with the patient to try to change them is fundamental to treating the true cause of disease (see earlier discussion of *tollem causum*).

Research demonstrated the importance of positive and negative thinking in heart disease and cancer, the two areas of disease that cause the highest death rate: doctors' health care management protocols should reflect this research in the same way that attention to proper diet is part of a management approach to high serum cholesterol. It is now clearly established, for instance, that even low levels of stress trigger the onset of myocardial ischemia.[203] We also know from the work of Steven Greer[204] and David Spiegel[205] that attitude and emotional exploration are critical to breast cancer survival. Knowing these scientific facts, all doctors must have strategies for helping their patients explore the areas of stress management, group therapy, and support groups and skills in building positive attitudes.

Implement Therapeutic Conditioning or Learning

> *Those who remain at least dimly aware that everything they say or do to a patient conveys a major or minor, positive or negative, and helpful or harmful psychological impact are likely to be more effective physicians.*[206]

Conditioning of the mind has been suggested as a mechanism by which the placebo effect becomes a learned response.[15,17,185] The future of therapeutic application of placebo will probably hinge primarily on the use of conditioning. A doctor who can understand this will pay close attention to the stimuli of his or her patients and modify these stimuli in a scientific way to help treat immune-related and neurologically related diseases.

Modern psychology acknowledges two models of conditioning or reinforcement of learning behavior, operant and classical. Operant conditioning is a behavior response that theoretically occurs in the presence of some stimulus that is a positive reinforcement; for example, a rat will learn to press a conditioning bar if a food pellet is dispensed as a result. Classical conditioning is a behavior response created by the simultaneous pairing of unconditioned and conditioned stimuli before an evoked response. This is best illustrated by the experiments of Pavlov and his "salivating dog." In Pavlov's experiment with the conditioning of a dog's salivary response to the ringing of a bell, the bell ring is the conditioned stimuli and the food is the unconditioned stimuli. The salivation is the unconditioned response to the food that becomes the conditioned response.

When the dog finally associates the bell ring with the food, the ringing alone causes salivation, the conditioned response.

The principle of classical conditioning has far-reaching implications for the diagnosis and treatment of disease because of the pervasive and permeating implications that conditioning has in all the sensory stimuli of daily existence, in sickness and in health: "Pavlov's teachings, concepts and basic notions afford the real and ultimately scientific basis for the recognition of the potentialities of medical science attacking diseases from both the psychic and somatic sides."[207]

For the purposes of this discussion, one must recognize that classical conditioning happens randomly in our environment and is closely linked to health and healing phenomena. Subconsciously, we note random events and associate them with previous events and observations, independent of an intended learning behavior. Operant conditioning happens in the context of reward, and classical conditioning happens in the context of associated stimuli. There is a much greater predominance and range of associated stimuli (classical conditioning) than operant conditioning for the genesis of the placebo effect. This is because the operant depends on reward, although operant conditioning can happen in the medical mode: "Pain-killing drugs that I have taken in the past kills pain; therefore this capsule, which is a painkiller, will kill my pain."

Gliedman et al[15] noted that drugs that affect the CNS are readily conditioned, whereas drugs that affect the peripheral nervous system and are secretory stimulators (e.g., atropine and pilocarpine) do not result in the establishment of a conditioned response. The primary importance of psychological states to CNS excitation demonstrates that the pivotal loci of command for conditioning reside within the hypothalamus and the limbic system. Therefore, a doctor who can induce a state of central excitation in the patient can encourage and condition the patient to make those changes that are deemed necessary for the recovery of health.

The conditioning of a patient to a placebo response is modified by learning stimuli associated with the illness, the stimuli of the doctor and the therapeutic setting, the stimuli of the therapy, previous health, medical therapy, and authority-related experiences.[208] The way that all of these factors interact in the psyche of the patient determines the nature of the placebo response that is achieved.

Satiation obscures the conditioned response, whereas situations of increased stress seem to potentiate the responsiveness of the placebo effect.[116] Placebo, conditioning, and learning may therefore be subject to the nature of central excitatory states as well as levels of stress and distress.

The physiologic breadth of the placebo response in humans can now be understood in terms of the variety of interactions and effects that drugs, therapeutic procedures, and sensory phenomena of the medical environment have on the psychosomatic matrix of a patient's consciousness. Rossi[17] noted that this complicated web of sensory processing revealed how any facet of therapy "that alters any aspect of the body's sensory, perceptual or physiologic responsiveness on any level can disrupt the more or less fragile state-dependant encoding of symptoms and thereby evoke a 'nonspecific' but real healing effect that we call the placebo response."

The scientific basis of therapeutic applications of psychoneuroimmunology is based on classical conditioning. Ader and Cohen[209] performed research to show that the immune system could be conditioned for therapeutic purposes. They conditioned immunosuppression in rats by injecting them with a conditioned stimulus of cyclophosphamide (a potent immunosuppressing agent) while feeding them a saccharine solution as an unconditioned stimulus.[209] The idea of conditioning for immunomodulation in human patients is therefore a promising therapeutic modality. Applying conditioning techniques for the treatment of systemic lupus erythematosus involving a dosage that normally had minimal results resulted in a delay in the development of the disease.[210]

To fully account for the extent of previous and future conditioning in a patient, the physician must take a complete and exhaustive history to explore the influences of family, work, accidents, emotional predispositions, medical history, and neutral stimuli as contributing factors during the onset of an illness. Lifestyle and emotional, behavioral, or physiologic factors might contribute to maintaining the state-dependent learning pattern of disease and dysfunction or give clues to a successful therapeutic intervention. A good example of this is the demonstration by Batterman and Lower[211] of increased analgesics effectiveness based on similar previous therapy. A physician who knows which therapies succeeded and which failed can take advantage of the patient's conditioning and encourage biochemical pathways that the body has learned. Drug or therapeutic interventions are not procedures that can be predicted in the same way that in vivo experimental results can.

The variables involved in human responses to therapy are clearly underestimated in the current rush of research-oriented therapeutic evaluation.[56] Therefore, a patient who has been treated by a number of physicians or practitioners for a complaint and has received no results or relief has been conditioned to believe that consultation and treatment by a physician will provide no positive changes. When the patient visits the next practitioner, even if this practitioner can offer a diagnosis and treatment that are correct answers to the long-sought cure, there are very real patient conditioning factors that must still be considered.

Consider the case of a young woman who underwent treatment for breast cancer and the clinical course of the ensuing metastases. Each time she had a positive response to therapy, she experienced a subsequent re-manifestation of the cancer. The result of this conditioning was that she came to equate each new course of chemotherapy as a herald of some new manifestation: she "was torn between a desire to live and the fear that allowing hope to emerge again would merely expose her to misery if the treatment failed."[212]

The parameters of conditioning in a clinical setting extend to all aspects of the patient's sensory perceptions. Consciously or unconsciously, the physician provides an environment for patient learning. Lipkin[213] pointed out that every drug, every apparatus, every injection, and every piece of information or advice carries a suggestion of help and hope, regardless of the physiologic effects that may accompany it. The physician must realize that patients are taking in all the information about the surroundings, interactions, and therapy and are making associations that can potentially affect the course of their responsiveness to therapy.

Mowrer[136] observed that the "safety signals" of syringes, lab coats, and behavioral procedures were all retained in the patient's psyche for future association. A physician can skillfully take advantage of these signals by encouraging and cultivating response generalization or by associating previous therapeutic situations with subsequent treatments by means of unconditioned stimuli, such as office music, odors, and images. Giving patients some sort of unconditioned stimulus that can be taken home allows them to associate with the conditioned response, eliciting the memory of the therapeutic interaction while patients are away from the doctor's office. These unconditioned stimuli or placebos can be given in multiples at one time,[131] changed for more powerful stimuli,[69] and delivered at the end of an induction, suggestion, or imagery procedure. They should not be limited to pills or other apparent

medicaments, but should extend to sounds, smells, visualizations, and feelings.

It should be remembered that therapeutic conditioning depends on a perceived physiologic shift or change in the patient as described in the theory and research of biofeedback.[214] This shift can be experienced as a sense of relaxation, increased warmth or circulation, altered autonomic tone, or change in some sensory perception. Patients know immediately when there is no change in their disease or dysfunction after they have been given placebo.[215] Therefore, some patients need a more active form of therapeutic management that allows for some level of perceived change. Ideally this perception would be a sense of being free from pain or alteration from a state of abnormal physiologic function to a state of improved physiologic function. Acupuncture, spinal manipulation, drug therapy, physiotherapy, hydrotherapy, and surgery are all therapies that can create an immediate biochemical impact perceived by the patient.

The optimum model to apply to the concept of conditioning therapy and the selection of an appropriate therapy or modality was proposed by Greene and Laskin[216] in their evaluation of myofascial pain dysfunction. During an 11-year follow-up study of patients with myofascial pain dysfunction, these researchers concluded that, when comparing the effectiveness of a wide variety of reversible and nonreversible (surgical) therapies, conservative and reversible therapies were the most important and appropriate treatment factors for the patient's health and well-being. Focusing on patient communication, educating patients about reversibility of the condition and the nature of muscle dysfunction as it relates to stress–pain–spasm, developing a therapeutic strategy based on increasing patient awareness and self-management skills, and selecting a flexible treatment strategy were all found to be essential for achieving a good initial response that could lead to long-term wellness. Greene and Laskin[216] believed that the specifics as to which therapy was most indicated were not as important as the need to focus on the nature of presenting musculoskeletal problems and the factors and complexity of the treatment environment.

Routine use of active pharmacologic substances reinforces the relationship between conditioned and unconditioned stimuli. However, routine use of unconditioned stimuli in the absence of a conditioned response weakens the therapeutic efficacy of the practitioner and has been described as "placebo sag."[16] Therefore, the learning of a conditioned response from unconditioned stimuli could diminish if the conditioned stimuli fail to produce an adequate or reliable conditioned response. Without the intermittent demonstration of active strength, the placebo effect will get weaker and weaker.

The implications of placebo sag for practitioners of alternative medicine, who try to work with the body's own defense mechanisms without overwhelming medical intervention, are that periodic use of perceptually active therapy is needed to support a patient who is not able to respond or responds too slowly to a gentler therapeutic nudge. In this case, the physician must recondition the vital force to open a path to homeostasis.

In a sense, this may be a paradigm of the therapeutic situation, in which changes toward health are induced in the patient by a doctor who is able to cultivate a basic state of arousal, presumably central in nature. This state of arousal causes the patient to become accessible to the doctor's expectations of the patient.[15]

The typical placebo burst, in which a therapy is initially effective after a short period but then wanes, is now understood in terms of the placebo sag from lack of effective unconditioned stimuli to maintain the conditioned framework.[69] Physicians who lack the ability to extract themselves from a series of unsuccessful therapies risk eventual placebo sag[16]:

> *[T]herapists who primarily use their active strengths (or unconditioned stimuli) paradoxically will get stronger placebo effects than quacks, will enjoy escalating credibility, and will seem as miracle men—when in fact perhaps only half their miracles can be traced to their active ingredients while the other half is a function of the anticipatory (or conditioned) response elicited by their conditioned features.*

Because the visit to a physician is often initiated by the physical pain of the patient, it stands to reason that skillful pain management is a high priority in establishing a therapeutic conditioned response. Pain management by hypnosis, transcutaneous electrical nerve stimulation, therapeutic touch, direct or indirect manipulation, imagery, acupuncture, meditation,[217] and an understanding that aims to elicit the nature of suffering[212] can all be valuable therapeutic adjuncts to establishing a therapeutic environment that conditions the patient for full potentiation of his or her healing capabilities. (See Chapter 42 for a full discussion of these techniques.)

With the recent development of standardization of, research into, and concentration of the active components of plant medicines, vitamins, and biochemical precursors, naturopathic medicine as well as other forms of alternative medicine stand on a stronger therapeutic base because of an ever-growing verification of its pharmaceutical and therapeutic armamentarium. These therapeutic modalities are characterized by safe yet physiologically active substances and procedures; therefore, they provide some defense against placebo sag.

Use Altered States of Consciousness

Since ancient times, aboriginal humans have recognized the tremendous therapeutic power that lays dormant in the subconscious mind. For thousands of years, shamans and medicine men used trance states to engage the most subtle aspects of the patient's subconscious to affect factors in disease pathogenesis and prognosis.[218] In modern medicine, it has been documented that shamanistic healing involving altered states can offer dramatic "spontaneous remissions"[31]; the mechanisms of this process have been explored in the theory and application of hypnosis.[3,128]

Most currently accepted techniques employed to trigger the subconscious to effect positive changes in somatic or psychic health involve hypnosis. Placebo effect has been linked with hypnosis, or "low arousal states," which are therefore believed to be critical factors in the evaluation of the mechanisms and perimeters of placebo.[207] A review of the literature documenting the potency of hypnosis and the observed results of placebo clearly demonstrated that these two areas yielded remarkably similar clinical results. The inquiry into hypnosis grew out of the simple intent to validate the effectiveness of the mind in healing processes, whereas most placebo literature grew out of the intent to demonstrate a certain percentage of chance, fluke, spontaneous remission, or psychosomatic illness as a factor to be ruled out in the delivery of intelligent, scientific health care. Using these antiquated definitions of placebo and hypnosis, one is led to believe that hypnosis describes a process of healing based on the skillful guidance of a qualified practitioner, and that placebo describes a process based on chance, regardless of the professional circumstances. On closer inspection, the distinction between the two blurs: they appear to be much the same process.

Illness, healing, and health states shift constantly in the homeostatic system, a system that is affected by stimuli received through the different levels of awareness and can be accessed, investigated, and modified by a variety of techniques. These include placebo, hypnosis, and induced altered states of consciousness. Rossi[17] noted that because memory depends on and is limited to the level of awareness in which the memory was acquired, it is "state bound information":

> *State dependent memory, learning, and behavior phenomena are the missing link in all previous theories of mind body relationships.… The major thrust of these hypotheses is that mind-body information and state-dependent memory, learning and behavior mediated by the limbic-hypothalamic system, are the two fundamental processes of mind-body communication and healing.… The new approach to mind-body healing and therapeutic hypnosis may be conceptualized as processes of accessing and utilizing state-dependent memory, learning and behavior systems that encode symptoms and problems and then reframing them for more integrated levels of adaptation and development.*

Some psychosomatic phenomena are coded into the behavior of an individual through state-induced patterning. Until the patient can access the state in which somatic complaints are induced, possibly through hypnosis or other methods that break the sympathetic dominance of "encoded" shock,[219] the psyche cannot clear them from the soma[17]:

> *A person in a traumatic car accident experiences an intense rush of the alarm reaction hormones. His detailed memories of the accident are intertwined with the complex psychophysiological state associated with these hormones. When he returns to his usual or "normal" psychophysiological states of awareness a few hours or days later, the memories of the accident become fuzzy or, in really severe cases … the victim may be completely amnesic. The memories of the accident have become "state-bound"—that is, they are bound to the precise psychophysiological state evoked by the alarm reaction, together with its associated sensory-perceptual impressions.*

In accessing these psychosomatic state-dependent areas of homeostatic dysfunction, the physician must use techniques that relax the conscious mind and allow access to subconscious content for reframing. The nature of the visit to a physician encourages a patient into more accessible unconscious states as demonstrated by higher placebo effects when patients present in a hospital setting.[169] These labile states of consciousness are quite natural; humans constantly cycle in and out of different consciousness states.[169] These cycles, or ultradian rhythms, are described as alternating cycles of hemispherical dominance that change every 1-½ hours.

When these cycles are interrupted by behavioral stress, psychosomatic behavioral responses such as ulcers, gastritis, asthma attacks, and rashes develop.[220] A change in these rhythms manifests as a period of psychic repose. If an individual is in the midst of performing a task, daydreaming or the perceived need for a rest or coffee break may be the external manifestation of an internally sensed signal of a change in rhythm. This is also a period when one is highly susceptible to hypnotic suggestion. Because these rhythms are very flexible and labile, they can be invoked through hypnosis, or if the physician senses a natural lull indicating a hemispherical switch, a "natural" trance can be induced.

Centuries ago in India, practitioners of hatha yoga observed the effect of mental states on the breathing patterns of an individual. With anger, frustration, and mental instability, the breath reflects a short, arrhythmic pattern that mirrors the disturbed psyche of the person. Conversely, when a person is in a peaceful, relaxed, deep meditative state, the breath is long, rhythmic, and barely perceptible. Their discovery formed the basis for the development of breathing exercises called *pranayama* (literally, regulation or restraint of the vital energy), which aimed to calm the breath so that deep states of meditation and focused concentration could be attained. Current research has affirmed the powerful effect these exercises have on asthma, diabetes, chronic gastrointestinal disorders, and psychosomatic and psychiatric dysfunction.[221]

Therapeutic exercises that use somatic stimuli to effect changes in the psyche create fertile environments for stimulating the placebo response. A breathing technique used to decrease sympathetic tone or alter nostril predominance for causing shifts in hemispherical activity,[222] an exercise to release fascial muscle tension and thereby effect mood-enhancing blood flow in the brain,[223,224] and a biofeedback treatment that aids in slowing the heart rate and decreasing negative emotional states[214] are all examples of how the psyche can be accessed by the soma. The whole process of eliciting the placebo response involves an attempt to marshal all the reserves and potential for healing through a doctor–patient interaction, engaging both the patient's mind and body to reestablish homeostatic equilibrium.

Health care professionals can use the wisdom of psychosomatic therapies as a central part of their therapeutic protocol. In addition to the specific therapeutic regimen, treatment of the whole patient can be achieved through these harmonious techniques. If physicians could persuade patients to care daily for their emotions, minds, and spirits the way they care for their hair or teeth, the effectiveness of any prescribed treatment would be greatly enhanced. As a primary therapeutic adjunct and important basis for preventive medicine, this line of treatment is all too often ignored.

ETHICS

It is important to remember that there are two forms of "conscious" placebo use by the physician. The use of placebo as a gentle therapeutic agent by a practitioner is very different from the use of placebo in a controlled trial in which the possibility of a known therapy is withheld in a treatment group. Some researchers believe that use of placebo in clinical trials breeches the Declaration of Helsinki, which states that every patient should be assured of the best proven diagnostic and therapeutic method.[225] The ethical problems of delivering health care in a research design, in which there is a possibility of favorable outcome and half of the group is denied access to this possible favorable outcome, make it a troubling issue.

The ethical use of placebo has also been questioned in an attempt to determine whether a physician should be deceiving patients during the process of healing.[226] Although some writers advocate a restricted use of pure and impure placebo because of its "deceptive" nature,[214] it becomes clear in a brief review of the current literature[5] that any argument for or against the use of placebo assumes the existence of medical procedures that are free of potential placebo effect. Brody[27] concluded that placebo can be called the "lie that heals." However, closer examination shows that it is not the lie that does the healing, but rather the relationship between the patient and doctor that stimulates a natural self-healing mechanism via psychological, symbolic, and biological intervention[27]:

> *For some time, medical science has looked almost exclusively at technical means of diagnosis and treatment; the doctor/patient*

relationship that forms the setting for their application has been naively viewed as a noncontributory background factor, relegated to the amorphous realm of the "art of medicine," or simply ignored. In this setting, the placebo effect has inevitably been viewed as a nuisance variable, interfering with our ability to elicit "clean data" from clinical trials; and deception in medicine has been seen either as an unimportant side issue or as a tolerated means toward an end. But as the doctor/patient is rediscovered as a worthy focus for medical research and medical education, the placebo effect assumes center stage as one approach to a more sophisticated understanding of this relationship.

A physician's correct understanding of the nature of placebo therapy has been observed as able to coexist with its inaccurate use and abuse.[43] It has been recommended, however, that: (1) pure placebo should not be prescribed unless the physician has examined the exact indications even more carefully than when prescribing specific therapy, and (2) to avoid missing a disease process that can be easily treated with an empirically proven protocol (e.g., vitamin B_{12}–deficient peripheral neuropathy), the physician should not relax a diagnostic protocol because a patient seems to be responding to placebo.[226]

The final ethical hurdle of placebo use, or for that matter any medical treatment, is the abuse of hope in the patient's path of healing. It is one thing to make a harmless recommendation that provides no therapeutic value, but another to subject a patient to known consequences of a dangerous procedure in the pursuit of a dubious outcome. Hope can be abused, leading the patient to experience unreasonable suffering.[227]

CONCLUSION

Health practitioners must be equipped with a better understanding of placebo therapeutics.[9,228] For many years now, the study of placebo has been recommended to doctors and other health care professionals. The ideal environment for the dissemination of the therapeutic implications of the doctor–patient relationship is in medical schools as a required part of the curriculum. After finding a pattern of misuse and misunderstanding about the nature and efficacy of placebo, Goodwin et al[43] recommended that better education might result in more effective placebo use.

In 1938, Houston[176] wrote of the need to reaffirm the art of medicine because he perceived a trend in medicine that invested in a concept of the therapeutic doctor–patient interaction as "undisciplined thought." Houston's remedy for the intellectual bias that viewed medicine as a "tight, fast-set science" was to emphasize the importance of psychobiology in medical schools[177]:

One of the most hopeful moves in medical education is teaching to first-year students the elements of psychobiology. A system of belief is implanted best in the young. It would be my suggestion that psychobiology be taught in the premedical years, that the doctor/patient relationship be the beginning of medical studies. A deep insight into this fundamental philosophy is a chief concern of the internist.

Attitude and Cardiovascular Health, *89*
Attitude and Self-Actualization, *89*
Clinical Aspects of Learned Optimism, *91*

INTRODUCTION

A positive mental attitude is one of the important foundational elements of good health. This axiom has been contemplated by philosophers and physicians since the time of Plato and Hippocrates. In addition to simple conventional wisdom, modern research has also verified the important role that attitude—the collection of habitual thoughts and emotions—plays in determining the length and quality of life. Specifically, studies using various scales to assess attitude, including the Optimism–Pessimism (PSM) scale of the Minnesota Multiphasic Personality Inventory (MMPI), have shown that individuals with a pessimistic explanatory style have poorer health, are prone to depression, are more frequent users of medical and mental health care delivery systems, exhibit more cognitive decline and impaired immune function with aging, and have a shorter survival rate compared to optimists.[1-8] One of the most recent studies involved a large cohort of 5566 people who completed a survey at two time points, aged 51–56 years at Time 1 and 63–67 years at Time 2. This survey included a questionnaire to determine positive psychological well-being by measuring self-acceptance, autonomy, purpose in life, positive relationships with others, environmental mastery, and personal growth. The results showed that people with low positive well-being were 7.16 times more likely to be depressed 10 years later.[9] This research highlighted the fact that although life is full of events that are beyond one's control, people can control their responses to such events. Attitude goes a long way toward determining how people view and respond to the stresses and challenges of life.

Attitude is reflected by *explanatory style*, a term developed by noted psychologist Martin Seligman to describe a cognitive personality variable that reflects how people habitually explain the causes of life events.[8] Explanatory style was used to explain individual differences in response to negative events during the attributional reformulation of the learned helplessness model of depression developed by Seligman (described in Chapter 142).

To determine a patient's level of optimism, have him or her take the Attributional Style Questionnaire developed by Seligman or use the PSM scale of the MMPI. Techniques to help patients learn to be optimistic are given in the following discussion.

ATTITUDE, PERSONALITY, EMOTIONS, AND IMMUNE FUNCTION

The importance of attitude to human health has been examined in the link among the brain, emotions, and the immune system. Research in the field of psychoneuroimmunology indicates that every part of the immune system is connected to the brain in some way, either via a direct nervous tissue connection or through the complex language of chemical messengers and hormones. What scientists are discovering is that every thought, emotion, and experience sends a message to the immune system that either enhances or impairs its ability to function. A simplistic view is that positive emotions, such as joy, happiness, and optimism, tend to boost immune system function, whereas negative emotions, such as depression, sadness, and pessimism, tend to suppress it.

Studies examining immune function in optimists versus pessimists have demonstrated significantly better immune function in the optimists. Specifically, studies have shown that optimists have increased secretory immunoglobulin-A function, natural killer cell activity, and cell-mediated immunity, which is demonstrated by better ratios of helper to suppressor T-cells than those of pessimists.[5,10-13]

The immune system is so critical to preventing cancer that, if emotions and attitude were risk factors for cancer, one would expect to see an increased risk of cancer in people

who have long-standing depression or a pessimistic attitude. Research supports this association; for example, smokers who are depressed have a much greater risk of lung cancer than smokers who are not depressed.[14]

Depression and the harboring of other negative emotions contribute to an increased risk of cancer in several ways. Most research has focused on the impact of depression and other negative emotions on natural killer cells. Considerable scientific evidence has now documented the link between a higher risk of cancer and negative emotions, stress, and a low level or activity of natural killer cells.[15] Negative emotions and stress paralyze many aspects of immune function and literally can cause natural killer cells to burst.[15,16] Furthermore, the prototypical cancer personality—an individual who suppresses anger, avoids conflicts, and has a tendency to have feelings of helplessness—has lower natural killer cell activity than other personality types.[12,13] These studies also indicate that individuals with a personality type that is prone to cancer have an exaggerated response to stress, which compounds the detrimental effects stress has on natural killer cells and the entire immune system.

Depression and stress not only affect the immune system but also appear to hinder the cell's ability to repair damage to DNA. Most carcinogens cause cancer by directly damaging DNA in cells, thereby producing abnormal cells. One of the most important protective mechanisms against cancer in the cell's nucleus is the enzymes responsible for the repair or destruction of damaged DNA. Several studies have shown that depression and stress alter these DNA repair mechanisms; for example, in one study, lymphocytes (a type of white blood cell) from depressed patients demonstrated impairment in the ability to repair cellular DNA damaged by exposure to x-rays.[17,18]

Just as research has identified personality, emotional, and attitude traits that are associated with impaired immune function, likewise the field of psychoneuroimmunology has identified a collection of "immune power" traits that include a positive mental attitude, an effective strategy for dealing with stress, and a capacity to confide traumas, challenges, and feelings to oneself and others.[15,19]

ATTITUDE AND CARDIOVASCULAR HEALTH

In addition to the brain and immune system, the cardiovascular system is another body structure intricately tied to emotions and attitude. The relationship of an optimistic or pessimistic explanatory style with incidence of coronary heart disease was examined as part of the Veterans Affairs Normative Aging Study, an ongoing cohort study of older men.[7] These men were assessed by the MMPI PSM scale. During an average 10-year follow up, 162 cases of incident coronary heart disease occurred: 71 cases of incident nonfatal myocardial infarction, 31 cases of fatal coronary heart disease, and 60 cases of angina pectoris. Men reporting high levels of optimism had a 45% lower risk for angina pectoris, nonfatal myocardial infarction, and coronary heart disease death than men reporting high levels of pessimism. Interestingly, a clear dose–response relationship was found between levels of optimism and each outcome.

To illustrate how closely the cardiovascular system is linked to attitude, one study showed that measures of optimism and pessimism affected something as simple as ambulatory blood pressure.[20] Pessimistic adults had higher blood pressure levels and felt more negative and less positive than optimistic adults. These results suggest that pessimism has broad physiologic consequences.

Excessive anger, worrying, and other negative emotions have also been shown to be associated with an increased risk for cardiovascular disease; however, these emotions may simply reflect a pessimistic explanatory style.

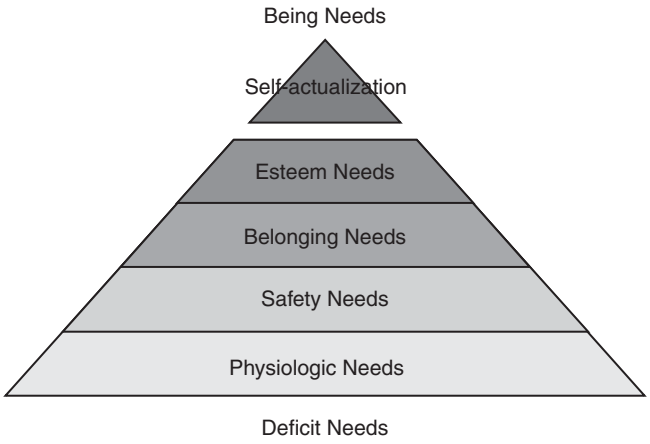

FIGURE 7-1 Maslow's hierarchy of needs.

ATTITUDE AND SELF-ACTUALIZATION

A physician's role should include not only facilitating the health of the patient but also helping the patient achieve *self-actualization*, which is a concept developed by Abraham Maslow, the founding father of humanistic psychology. His work and theories were the result of intense research on psychologically healthy people over more than 30 years. Essentially, Maslow was the first psychologist to study healthy people. He strongly believed that the study of healthy people would create a firm foundation for the theories and values of a new psychotherapy.

Maslow discovered that healthy individuals are motivated toward self-actualization, a process of "ongoing actualization of potentials, capacities, talents, as fulfillment of a mission (or call, fate, destiny, or vocation), as a fuller knowledge of, and acceptance of, the person's own intrinsic nature, as an increasing trend toward unity, integration, or synergy within the person."[21]

Maslow developed a five-step pyramid of human needs in which personality development progresses from one step to the next. The needs of the lower levels must be satisfied before the next level can be achieved. When needs are met, the individual moves toward well-being and health. Figure 7-1 displays Maslow's hierarchy of needs.

The primary needs that form the base of the pyramid are basic survival or physiologic requirements: the satisfaction of hunger, thirst, sexuality, and shelter. The second step consists of the needs for safety, which are essential for dealing with the world: security, order, and stability. The individual then progresses to the third step, which involves the ability to love and be loved: belonging. The fourth step involves self-esteem and self-respect: approval, recognition, and acceptance. The final step is self-actualization: the use of one's creative potential for self-fulfillment.

In modern life, a person's occupation often correlates with the ability to achieve these needs. Table 7-1 provides an application of Maslow's hierarchy of needs in an occupational environment.

Maslow studied and noted that self-actualized people had strikingly similar characteristics. Here are some of Maslow's key findings in an abbreviated form:

- Self-actualized people perceive reality more effectively than others and are more comfortable with it. They have an unusual ability to detect the spurious, the fake, and the dishonest in personality. They judge experiences, people, and things correctly and efficiently. They possess an ability to be objective about their own strengths, possibilities, and limitations. This self-awareness enables them to clearly define values, goals, desires, and feelings. They are not frightened by uncertainty.

TABLE 7-1 **Practical Application of Maslow's Hierarchy of Needs**

LEVEL OF NEED	GENERAL REWARDS	OCCUPATIONAL FACTORS
Self-actualization	Growth	Challenging job
	Achievement	Opportunities for creativity
	Advancement	Achievement in work
	Creativity	Promotion
Self-esteem	Self-respect	Social recognition
	Status	Job title
	Prestige	High status of job
		Feedback from the job itself
Belonging	Love	Work groups or teams
	Friendship	Supervision
	Belongingness	Professional associations
Safety	Security	Health and safety
	Stability	Job security
	Protection	Contract of employment
Physiologic	Food	Pay
	Water	Working conditions
	Sleep	
	Sex	

- Self-actualized people have an acceptance of self, others, and nature. They can accept their own human shortcomings without condemnation. They do not have an absolute lack of guilt, shame, sadness, anxiety, and defensiveness, but they do not experience these feelings to unnecessary or unrealistic degrees. When they do feel guilty or regretful, they do something about it. Generally, they do not feel bad about discrepancies between what is and what ought to be.
- Self-actualized people are relatively spontaneous in their behavior and even more spontaneous in their inner life, thoughts, and impulses. They are unconventional in their impulses, thoughts, and consciousness. They are rarely nonconformists, but they seldom allow convention to keep them from doing anything they consider important or basic.
- Self-actualized people have a problem-solving orientation toward life instead of a self orientation. They commonly have a mission in life, some problem outside themselves that enlists much of their energies. In general, this mission is unselfish and is involved with the philosophical and ethical.
- Self-actualized people have a quality of detachment and a need for privacy. Often it is possible for them to remain above the battle, to be undisturbed by what upsets others. They are self-governing people who find meaning in being active, responsible, self-disciplined, and decisive rather than being pawns or helplessly ruled by others.
- Self-actualized people have a wonderful capacity to appreciate the basic pleasures of life, such as nature, children, music, and sex, again and again. They approach these basic experiences with awe, pleasure, wonder, and even ecstasy.
- Self-actualized people commonly have mystical or "peak" experiences, times of intense emotions in which they transcend the self. During a peak experience, they have feelings of limitless horizons and unlimited power while simultaneously feeling more helpless than ever before. There is a loss of place and time, and feelings of great ecstasy, wonder, and awe. The peak experience ends with the conviction that something extremely important and valuable has happened, so that the person is transformed and strengthened by the experience to some extent.
- Self-actualized people have deep feelings of identification with, sympathy for, and affection for other people despite occasional anger, impatience, or disgust.
- Self-actualized people have deeper and more profound interpersonal relationships than most other adults, but not necessarily deeper than children's. They are capable of more closeness, greater love, more perfect identification, and more erasing of ego boundaries than other people would consider possible. One consequence is that self-actualized people have especially deep ties with relatively few individuals, and their circle of friends is small. They tend to be kind or at least patient with almost everyone, yet they speak realistically and harshly of those who they feel deserve it, especially hypocritical, pretentious, pompous, or self-inflated individuals.
- Self-actualized people are democratic in the deepest possible sense. They are friendly toward everyone, regardless of class, education, political beliefs, race, and color. They believe it is possible to learn something from everyone. They are humble, in the sense of being aware of how little they know in comparison with what could be known and what is known by others.
- Self-actualized people are strongly ethical and moral. However, their notions of right and wrong and good and evil are often unconventional. For example, a self-actualized person would never consider segregation, apartheid, or racism to be morally right although it may be legal.
- Self-actualized people have a keen, unhostile sense of humor. They do not laugh at jokes that hurt other people or are aimed at others' inferiority. They can make fun of others in general or of themselves when they are foolish or try to be big when they are small. They are inclined toward thoughtful humor that elicits a smile, is intrinsic to the situation, and is spontaneous.
- Self-actualized people are highly imaginative and creative. The creativeness of a self-actualized individual is not of the special talent type, such as Mozart's, but rather is similar to the naive and universal creativeness of unspoiled children.

CLINICAL ASPECTS OF LEARNED OPTIMISM

The new psychology that Maslow's work referred to may turn out to be "positive clinical psychology".[22] This field of practice was born in 1998 when Martin Seligman chose it as the theme for his term as president of the American Psychological Association.[23] Positive clinical psychology aims to change clinical psychology to have an equally weighted focus on both positive and negative functioning.[24] The approach is based on five key bodies of empirical findings: (1) the absence of positive well-being leads to the development of disorder over time[9]; (2) the absence of positive characteristics predicts disorder above and beyond the presence of negative characteristics[9]; (3) positive characteristics interact with negative life events to predict disorder (so studying only negative life events would produce misleading results)[25]; (4) many aspects of well-being range from extremely negative functioning, through a neural midpoint, to positive well-being (possibly including happiness to depression and anxiety to relaxation continuums),[26] making it impossible to study exclusively negative or positive well-being; and (5) positive interventions can be as effective as other more commonly used approaches such as cognitive therapy.[27]

Positive clinical psychology ultimately involves helping patients become optimistic, which according to Martin Seligman, the world's leading authority on attitude and explanatory style, is our natural tendency.[28] Optimism not only is a necessary step toward achieving optimal health, as emphasized in the preceding, but is also critical to happiness and a higher quality of life.

In many instances, it is not what happens in one's life that determines one's direction; to a large degree, it is the response to those challenges that shapes the quality of life and determines one's level of health. Surprisingly, it is often true that hardship, heartbreak, disappointment, and failure serve as the sparks for joy, ecstasy, compassion, and success. The determining factor is whether these challenges are viewed as stepping stones or stumbling blocks.

A person's attitude is like his or her physical body: it must be conditioned to be strong and positive. Conditioning an attitude to be positive and optimistic requires adopting specific healthy habits. Here are four key areas of focus for helping patients develop a positive mental attitude:

- Help them become aware of self-talk. Tell them that all people conduct a constant running dialogue in their heads. In time, the things people say to themselves and others percolate down into their subconscious minds. Those inner thoughts, in turn, affect the way people think and feel. Naturally, a steady stream of negative thoughts will have a negative effect on a person's mood, immune system, and quality of life. The cure is to become aware of self-talk and then to consciously work to feed positive self-talk messages to the subconscious mind.
- Help them ask better questions. The quality of a person's life is equal to the quality of the questions habitually asked. For example, if a person experiences a setback, does he or she think "Why am I so stupid? Why do bad things always happen to me?" or "Okay, what can be learned from this situation so that it never happens again? What can I do to make the situation better?" Clearly, the latter response is healthier. Regardless of the situation, asking better questions is bound to improve one's attitude. Some examples of questions that can improve attitude and self-esteem when asked regularly include:
 "What am I most happy about in my life right now?"
 "What am I most excited about in my life right now?"
 "What am I most grateful about in my life right now?"
 "What am I enjoying most in my life right now?"
 "What am I committed to in my life right now?"
 "Who do I love? Who loves me?"
 "What must I do today to achieve my long-term goal?"
- Help them set positive goals. Learning to set achievable goals is a powerful method for building a positive attitude and raising self-esteem. Achieving goals creates a success cycle: a person feels better about himself or herself, and the better he or she feels, the more likely he or she is to succeed. Some guidelines for helping patients set health goals follow:
 State the goal in positive terms and in the present tense; avoid negative words. It's better to say, "I enjoy eating healthy, low-calorie, nutritious foods" than to say "I will not eat sugar, candy, ice cream, and other fattening foods."
 Make the goal attainable and realistic. Start out with goals that are easily attainable, like drinking six glasses of water a day or switching from white to whole-grain bread. Initially choosing easily attainable goals creates a success cycle that helps build a positive self-image. Little things add up to make a major difference in the way a person feels about himself or herself.
 Be specific. The more clearly the goal is defined, the more likely it will be achieved. For example, if a person wants to lose weight, he or she should define the desired weight and the body fat percentage or measurements to be achieved.
- Help them experience gratitude. A large body of recent work has suggested that people who are more grateful have higher levels of well-being, are happier, less depressed, less stressed, and more satisfied with their lives and social relationships.[29,30] Gratitude appears to be one of the strongest links with mental health of any character trait. Helping to instill a sense of gratitude has been shown to be a very successful intervention. In one study, participants were randomly assigned to one of six therapeutic interventions designed to improve the participant's overall quality of life.[31] Of these six interventions, it was found that the biggest short-term effects came from a "gratitude visit," where participants wrote and delivered a letter of gratitude to someone in their life. This simple gesture showed a rise in happiness scores by 10% and a significant fall in depression scores, results which lasted up to 1 month after the visit. The act of writing "gratitude journals," in which participants wrote down three things they were grateful for every day had longer lasting effects on happiness scores. The greatest benefits with this practice were usually found to occur around 6 months after it began. Similar practices have shown comparable benefits.

Counseling is necessary for the severely pessimistic individual. Forms of cognitive therapy appear to be the most useful therapy at this time. Cognitions comprise the whole system of thoughts, beliefs, mental images, and feelings. Cognitive therapy can be as effective as the use of antidepressant drugs in the treatment of moderate depression; in addition, there tends to be a lower risk of relapse—the return of depression—with cognitive therapy.[32] One reason for this is that cognitive therapy teaches people practical skills they can use to combat depression any time, anywhere, and every day for the rest of their lives. Cognitive therapy avoids the long, drawn out (and expensive) process of psychoanalysis. It is a practical, solution-oriented psychotherapy that teaches skills a person can apply to improve quality of life.

Mental health specialists trained in cognitive therapy seek to change the way the depressed person consciously thinks about failure, defeat, loss, and helplessness. To do so, they employ five basic tactics that help patients to do the following:

- Recognize the automatic negative thoughts that flit through consciousness at the times when they feel the worst.
- Dispute the negative thoughts by focusing on contrary evidence.
- Learn a different explanation to dispute the automatic negative thoughts.
- Avoid rumination (the constant churning of a thought in one's mind) by helping the patient better control his or her thoughts.
- Question depression-causing negative thoughts and beliefs, and replace them with empowering positive thoughts and beliefs.

WHAT IS NATURAL MEDICINE?

For the purposes of this chapter, *natural medicine* is defined as a paradigm of healing found throughout the world and guided by several distinguishing principles. Care is patient-centered and individualized. Emphasizing self-care, natural medicine supports the body's own healing processes and treats causes rather than simply alleviating symptoms. Natural medicine distinguishes itself by an affinity for medicines and health aids from the natural environment (e.g., those with which human beings have co-evolved). Despite the preference for remedies from nature, natural medicine is a practice. Much of what is now called complementary and alternative medicine (CAM) fits the definition of natural medicine. This chapter addresses those CAM practices and systems that have a discernable set of strategies and observable health outcomes. Under proper social cultivation, such practices may evolve to be internally coherent and efficient, although the theories governing them may not be well articulated. The skills are distributed over numerous professional groups (e.g., naturopathic doctors, traditional eastern and southern Asian medical systems, mixer chiropractors, and practitioners of many indigenous medicines), and are also practiced widely among conventional medical doctors (as integrative or functional medicine) and other eclectic healers. Some traditional practices have evolved parallel to what modern medicine has become, resulting in regulated disciplines. Natural medicine may be of aid to ameliorate disease and improve health, perhaps in a revolutionary way. By contrast, some practices may be harmful sociocultural delusions. How does one tell the difference?

There have been a great many published reviews of natural medicine practices, especially of its substances and approach to diseases, including the present volume.[1-3] Nevertheless, many of its practices have not borne the level of scrutiny of standard modern medicine. Some within CAM ranks have resisted the usual scientific evaluation as reductionistic and an inappropriate means to the understanding of healing.* This chapter addresses needs in the development of relevant original data in natural medicine.

PURPOSE OF RESEARCH

The improvement of healing practices is the general purpose of health research. An improvement could be clinical (with which individual patients may be helped) or economic (in which society's abilities to reduce total suffering and maximize health are enhanced). Various parts of the community (e.g., consumers, practitioners, government, industry) hope for research to respond to the questions "Does it work?" "Does it work better?" and "What works best?" To respond, one should know what "it" is (learned through observation and qualitative research) and what "works" means (the measures of the reduction of suffering and improvement of performance).

Research tools such as descriptive statistics and hypothesis testing are epidemiologic techniques; they lead to generalizations about populations. They have limitations in clinical practice, in which the focus is on one patient at a time. Current biomedical research increasingly focuses on strategy developed from molecular (lately genetics and the "-omics") and physical (surgical and prosthetic) models. In

*Editor Joseph Pizzorno comments, "I have asserted for over 30 years now that we do research not to prove ourselves, but rather to get better. How do you know if your therapy, no matter how natural, is actually helping rather than harming the patient unless you do objective research?"

research practice, hypothesis testing is usually most sensitive to a selected outcome and most internally valid (able to answer the precise question it set for itself) when it is most reductionistic. The more discrete variables of chemistry and mechanics lend themselves to more reductionistic hypothesis testing. In turn, the validity of the reductionistic approach depends on the precision (narrowness) of the question. Natural medicine is ecologic and holistic in its orientation, with numerous broad analog inputs and outputs with what might appear to be intuitive discriminations. The common models in research that emphasize transferability, internal validity, replicability, and generalizability in molecular and physical systems may conflict with model validity when studying natural medicine systems.[4] Model validity ensures that the study design reflects the structure and logic of the practices of interest. Thus, one might ask whether alternative medicine calls for alternative science. It may be so; some philosophers of science and mathematicians are working toward methods that may be better suited to the evaluation of natural medicine systems.[5,6] Although the development of accepted research methods that incorporate more complex and subtle biomedical quanta are awaited, much can be done with the currently available biomedical research tools.

METHODOLOGICAL PROBLEMS AND STRATEGIES

Medical research rightly results in a generalizable approach to human degeneration and injury. Thus, one can expect to do research only with medical practices that are defined and transferable to other practitioners and patients. Successful research determines whether it is true that interventions produce benefit and how reliable they are in their effects. Research needs to be replicable to evaluate a therapy for potential promulgation and thus qualify for social support. The obvious is stated here because studies of natural medicine may have difficulty achieving these well-accepted research ideals.

What does replicability mean for a medicine that may offer individualized treatment to every patient? How does individualized treatment map onto an evaluative system in which outcomes typically refer to populations? Better tools are needed to understand and evaluate these practices, particularly informational tools that go beyond the more commonly used physiologic, psychological, pharmaceutical, and epidemiologic methods.[5] Many accommodations within clinical study methodology can be made that will reduce the apparent contradictions of the different medical value systems. Research methods from other fields like psychology, ecology, and anthropology can also be used. When performing research studies in natural medicine that might lead to improved practice, issues that are different from or need more emphasis than those in conventional biomedicine will need to be addressed. This chapter touches on some of the methodological issues for clinical trials, observational studies, and basic science studies in natural medicine.

Clinical Trials

Properly performed clinical research in conventional medicine is a demanding discipline that encompasses study design; determination of sample size and population characteristics; ethics; clinical care; definition and sensitive measurement of diseases and outcomes; project management, recruitment, and participant adherence and retention; and data management and statistics, analysis, and interpretation. All of these are secondary to establishing the research questions—the purposes—of the trial which will differ, for example, in explanatory (development and discovery: Could this work in controlled circumstances? How?) versus pragmatic (application and policy: Does this work in everyday practice? Which treatment is better?) study.[7] Different designs can be usefully applied in research approaches to different aspects of natural medicine practice. For any type of clinical trial of natural medicine, the following issues bear additional attention beyond those required for pharmaceutical trials:

1. Standardization
2. Individualization of treatment: nosology and indications
3. Combination therapies: effect size and safety
4. Nonspecific healing effects
5. Outcomes and measures
6. Controls and blinding
7. Whole practice models

Different clinical trial methods should also be considered, including for fit with currently important questions in natural medicine: (1) efficacy trials that are randomized and placebo controlled, (2) comparative trials that test treatments against each other, and (3) pragmatic trials where conditions model everyday practice to the extent possible.

Standardization

Replicability is a hallmark of the scientific method. Specifically what is tested (e.g., a substance, treatment procedure, or system of practice) must be defined, described, and stabilized so that it can be delivered reliably from patient to patient and study to study. Standardization is a great strength of modern medicine's pharmacotherapeutics. Natural medicine does not have as definitive a codex. Rather, its practices evolve over time, with some areas highly dependent on current scientific discovery, whereas others are used empirically, rather than rationally, in procedures that are hundreds or thousands of years old.

The organized natural medical professions have variably definitive articulations of philosophy and clinical strategies. What constitutes a competent practitioner in a given discipline often remains uncertain,[8] and many natural medicine approaches, like those of indigenous practices, are unlikely ever to be codified. Even with the licensed practices (e.g., naturopathic medicine, acupuncture, and chiropractic), health insurance coverage with regulation by practitioner-review panels is recent. It is only in the last two decades that coding systems for alternative practices have begun to describe the array of interventions available in the United States.[9] The current emphasis on research in CAM practices calls for speeding up the process of standardization toward replicability.

Communication about natural medicine research issues can be problematic when using standard clinical practice and biomedical research metaphors. One way to understand the problem is to say that natural medicine's critical practices lack articulation and operationalization of accepted and, within the respective practitioner groups, widely understood memes. Memes are collective concepts: ideas, behaviors, or skills that are transferred from one person to another by imitation and replicable on a population basis (see Richard Dawkins' book *The Selfish Gene*, from 1976)[9a]. A meme, as a phrase, invokes meaning beyond those of the words themselves, such as in the principle *vis medicatrix naturae* (the healing power of nature). Dictionaries of memes may be needed for the collective concepts of natural medicine practice that may be identified as the practices are investigated. The development of memes through which to express the syncretic concepts of natural medicine and which may have broad applicability is one of the benefits of researching the practices.[5] The dearth of articulation of natural medicine's concepts accounts in part for its remarkable variation among practitioners. Its transfer from mentor to student may be imprecise or misinterpreted even before practitioner

preferences and personalities are brought into play. This is not to say that the concepts of natural medicine practice are not reliably transmitted from mentor to student, only that they are not yet always articulated in ways that have been operationalized for clinical trials.

Standardization of natural remedies is becoming better understood. To perform a single-agent controlled trial of herbs in a specific disease, numerous choices should be made about the intervention. The Policy Announcement on the Quality of Natural Products of the National Institutes of Health (NIH) National Center for Complementary and Alternative Medicine (NCCAM) has brought some clarity to the botanical standards for NIH sponsored trials (http://www.nccam.nih.gov/research/policies/naturalproducts.htm). Studies should begin with verification of plant species used, growth and harvesting conditions, and the stability of purported active compounds. Selections should be made among plant parts, various crude extracts, or specific chemical constituents that may be concentrated in various ways and to varying degrees of purity. Crude fresh extracts, which traditional herbalists prefer, are highly susceptible to deterioration. In more sophisticated systems of botanical medicine preparation, a product is standardized to guarantee the minimum or maximum concentration of a number of ingredients for a given period, for example, EGb 761 (Schwabe GmbH, Karlsruhe, Germany), the *Ginkgo biloba,* which has been the most researched botanical and is standardized on four constituents. Standardizing on particular constituents has its challenges. Active ingredients in plants are often classes of molecules (e.g., polysaccharides, saponins, terpenes) that are difficult to distinguish in biological activity. Different compounds in a single species may have similar, possibly complementary effects, such as the polysaccharides and isobutyramides in *Echinacea* species. During in vitro assays, which guide fractionation of the crude extract toward a single active molecule, it is not uncommon for activity to increase but then diminish as greater purity of an identified molecular species is reached, as was the case of the terpenes of *Andrographis paniculata* (AndroVir, Paracelsian, Inc., Ithaca, NY) in cell signaling. A few botanicals are standardized on an in vitro biological activity. The industry standard, porously applied, is chemical standardization on actives and certified Good Manufacturing Practices.

Nutrition can be divided into dietary practices and nutritional supplements. Studies in dietary interventions are demanding. The gold standard for dietary intervention is a residential facility to maintain adherence to the therapeutic regimen, but this solution is expensive and recruitment is difficult. A long observation time is frequently needed in dietary studies because diets are often intended as preventives or restoratives.

Some nutritional supplements are cultures, such as probiotics (live bacteria taken to normalize commensal bacterial populations) and algae. Studies in these types of interventions have some of the same complications as botanical medicine studies, as well as the issues of organism viability and interactivity with commensal microorganisms and the internal conditions for proliferation.

Homeopathy is a special case in standardization, in that chemical standards are largely irrelevant for remedies that rely on ultradilutional remedies that may contain no molecules of the material originally potentized. Biological testing of homeopathics is in its infancy, and reliability is not ensured. Thus, only the manufacturing process can be standardized at this time.

"Body, mind, spirit" is a leitmotif of natural medicine. The interplay of psychodynamic and spiritual phenomena and physical health are only partially encompassed by the behaviorist approach of most health psychology research, but this has been greatly augmented by recent studies in "mind–body" medicine with numerous reviews in various specialties in publication. Advances have been made in the neuroscience of expectancies in the placebo effect, with the size of the placebo effect recognized as different in different conditions, but despite the ubiquitous use of placebo in practice,[10] operationalization and manipulation of placebo effects remain fraught methodologically and ethically. Placebo use in medical encounters continues to be explored, but raises more questions than answers;[11] however, hope remains for advances in future studies.[12]

While they represent a small proportion of all health studies, questions about spirituality remain of investigative interest, although with few authoritative and widely used research methods. Operationalization of spiritual experience is likely to be idiosyncratic or culture specific. The 4th edition of the *Diagnostic and Statistical Manual* (DSM-IV, 1995) reinstated the possibility of a religious or spiritual problem. Definitions of spirituality in the medical literature may refer to hope and meaning or to a personal relationship with God, serenity, or connectedness, all perhaps related to states of the patient's consciousness.[13,14] A number of thinkers continue to bemoan the lack of definition in the area.[15] Although efforts to present cogent, broadly acceptable definitions have been made, they have not been successful.[16,17] Better approaches to specifying spiritual interventions may be needed before they will be accessible to replicable research. Recent reviews of the health effects of intercessory prayer, an observable phenomenon, have been equivocal.[18]

Individualization of Treatment

Natural medicines' disease taxonomies (classifications of human illness) are not always congruent with those of Western molecular biomedicine. Primary variance (differences in outcome) of efficacy is more likely to vary with the conditions of a practice's native taxonomy than with a foreign one. For example, "strengthening the immune system," "decreasing toxicity," and "fortifying the will to health" are common goals in natural health therapeutics but are rare in conventional practice. Treatment response would be expected to have a different profile because different diseases are being treated. Thus, the speed to healing, as well as the disease being treated, may be confounded in the evaluation of one system by the other's definitions and rules. These concepts are themes to be described more explicitly in natural medicine diagnosis.

Some natural medicine concepts may no longer have or may never have had a biomedical equivalent. An example is the concept of "constitution" used in naturopathy, homeopathy, and Asian medical systems. This is a patient's given biological potential, tendencies, and patterns of long-standing psychophysical strengths and weaknesses that are genetically and embryologically determined. Others are the "biological terrain" (the background physical health and individual context for the immediate medical problem) and the "vital force" (the motive plan or spirit animating mind and body expressed as physiologic and psychological functionality and adaptability). Biomedical equivalents exist in some parameters for system control concepts; however, they are therapeutically exploited more thoroughly by holistic practitioners. Such concepts are balance (as in the immune system, among microbial symbionts, hormones, and neurotransmitters); deficiency (not just nutritional but organ deficiencies, such as hypochlorhydria and hypothyroidism); functional reserves; endogenous and exogenous toxicities; and dysmetabolisms (e.g., syndrome X). An important concept is that a disease syndrome may be an attempt by the body to adapt to ecologic stress and so should not be unnecessarily suppressed. This is of interest not only because it is

an independent variable (baseline factor), but also because it influences the measurement of the dependent variable (outcome).

A skilled natural medicine practitioner necessarily expects success through individualization of treatment regimens. Individualization means that remedies are prescribed not solely on the basis of disease entities but also according to other characteristics of the patient. Such characteristics may be transient, constitutional, or representative of the entire constellation of the patient's health problems, strengths, and his or her capacity for self-care. The lack of fit of a person's health syndrome with a conventional disease model, expressed perhaps in the inability or reluctance of a conventional practitioner to diagnose a particular health problem, may be the very reason a patient turns to natural medicine. A medical system that does not recognize an entity is unlikely to have an effective therapy for it. The complaint will be managed as something else, resulting in ineffective treatment while exposing the patient to the side effects of the "remedy." Conversely, a medical system that provides an adequate explanatory model for a patient's symptoms—their origin, aggravators, and ameliorators—has a better chance of effective treatment or management of the condition. Thus, individualization of treatment is a strength of natural medicine rather than merely a research problem. Compromises may be made in practice to make a trial of specified therapy possible, such as by semi-protocolized treatments, but they may alter therapeutic effect. If the need for individualization is neglected in natural medicine research design, the design will fail to apply the medicine as practiced and thus to evaluate its potential benefit.

Combination Therapeutics: Effect Size, Response Rate, and Safety

Combination treatment is almost a rule among natural medicine practitioners, who use multiple remedies individualized for each case. This complicates the design of clinical trials, yet the evaluation of combination interventions is critical to assessing an examined practice. Single natural agents may have a true effect small enough that a very large patient sample size is necessary to detect a treatment difference. However, the size of the effect of several agents acting together, especially if they act by different mechanisms, may work by cumulative or synergetic interactions. Combination treatment may also afford the practitioner latitude in choosing the correct remedies for a patient's condition, thereby increasing the treatment responder rate. Another strategy in choosing elements of combinations is tailoring them to a case to efficiently address multiple conditions simultaneously, thereby achieving better global outcomes. Yet another is to use some agents as "governors" (the term in Chinese herbal medicine) to ameliorate potential side effects of primary remedies.

The possibility of adverse events could theoretically rise with combinations. Although the problems of additive and synergetic actions, inhibition, and toxicity associated with multiple synthetic and novel pharmaceuticals in combination are both formidable and ubiquitous, the history of use of natural remedy candidates and the experience of clinicians in using combinations of natural products in various clinical populations mitigate these problems in everyday practice. For example, when whole botanicals are used at a traditional use dose, early toxicity is most likely to result in nausea and vomiting or diuretic action. More serious adverse events (e.g., anaphylactoid reactions) are rarer with nutrients and botanicals of traditional medicinal use than with novel drugs of a single molecular species. Modern practitioners of natural medicine also combine modalities (e.g., homeopathy and counseling, or manipulation and herbs) that are extremely unlikely to lead to a deleterious interaction, but that, if successful, could each stimulate improvement by a completely different route. Because of the breadth of options for affecting a condition, a skilled practitioner can avoid remedies that pose a risk in a particular case while still attaining the targeted pharmacologic action. There is no systematic study of the safety of combinations, but data from licensing authorities and professional liability companies for practices covered show modest levels of adverse experience.

Nonspecific Healing Effects

A confounder in a clinical trial is an apparent therapeutic effect that can be attributed not to the test treatment but to a factor associated with the treatment, disease, or population studied. This is a risk inherent to all research and is the reason why randomization, blinding, and objective measures are valuable in distinguishing true differences in effect among medications. The most honest scientists may have conscious or unconscious behaviors that could bias study results if differentially applied to study groups. Yet similar behaviors are at work in everyday clinical practice to induce affiliation, confidence, commitment, and satisfaction in patients and are the responsibility and *sine qua non* of skilled healers.

An important confounder that may be integral to treatment is intentionality. (See Chapters 6, Placebo and the Power to Heal and 7, Positive Mental Attitude.) The potential therapeutic action of pure intention, which is not mediated by language or any well-known material force, might be espoused explicitly by only a minority of holistic practitioners, although actually it might be widely practiced among them. This may be called "psychic healing" or simply "healing". If the intent is to determine whether these techniques have effect on disease, surprisingly, there may be no particular difficulties in conducting studies than those already addressed here. Trials of intercessory prayer may provide a model.[19] Design differences may be called for if the therapists are special (gifted) versus ordinary people, or if the healing energy is directed or willed versus invoked (as from God or spirits). Little has been written on the capacity of intention to influence physical outcomes; there is implicit rejection of the idea based on cartesian mind–body duality. Nevertheless, a number of studies suggest its existence.[20,21] Studies of the effect of prayer or other spiritual practices also may be relevant here and raise the possibility that specific kinds of intentionality may make a difference.[22]

Intuition is a similarly nebulous practitioner-associated quality that may have an influence on outcome. It might be thought to bear on diagnosis as a source of data or on therapeutics as a guide among possible alternative strategies. Although intentionality and intuition are not typically listed in the educational catalogs of natural medicine academic institutions as requisite health care skills to be acquired, they may be common concepts in the culture of the institutions. Generally they are not considered antiscientific concepts that should be expunged from the awareness of students. They might be acknowledged and even honored as possible sources of data and therapeutic direction as long as their "discoveries" are not contradicted by harder evidence. The informality of the inclusion of intention and intuition in practice compounds the difficulty of including these concepts in some reproducible way in research protocols.

Health care is practiced within a culture whereby practitioners and patients have roles and expectations that reinforce belief in expected outcomes. Some studies have indicated that good practitioner–patient communication results in better health outcomes. Thus, some of the magnitude of effect may depend on the setting in which care is offered. Differences in outcome between medical practices may also hinge on the difference between research and nonresearch settings. For example, it is possible that research

participants who refuse random assignment have a psychological orientation that may work synergistically with the physical effects of the practices of a medical culture that they prefer or to which they are native. If this is true, the evaluation of systems of practice relative to each other would preclude simple randomization. Trials that should be of real interest to policymakers are those that determine not simply whether a practice works for anyone to whom it is applied, but whether it works (and is cost effective) among those who choose it. A study design that could determine the added value of the availability of some form of natural health care in those who choose it would be one that randomly assigns patients to either a group that undergoes further randomization to strict assignment of alternative or conventional care or a group offering them a choice of alternative or conventional care.[23] Such a four-group trial including randomization with choice would compare the effect of the different practices among those patients who discriminatively select among them versus those who are simply assigned to them.

Natural medicine has little language for placebo and other nonspecific healing effects despite the fact that many conventional scientific authorities think this is an area in which there is much to offer. Both unintentional nonspecific healing effects and intentional psychospiritual medicine are areas in which the discovery and definition of important memes, especially those that may serve research, are poorly evolved not only for natural medicine, but also for Western biomedicine.

Outcomes and Measures

Because natural medicine addresses the holistic, it is expected by practitioners to have broad benefit (e.g., correcting deficiencies, strengthening and balancing metabolic processes, and "removing the obstacles to cure"). If a natural medicine intervention for a particular disease is shaped and delivered, a benefit is likely to affect more than one disease condition at a time. Randomized clinical trials (RCTs) are typically designed to provide higher validity on a few measures and tend to overlook effects on diseases other than the target disease, neglecting effects on overall well-being. (See discussion on "Cure and Suppression" in Chapter 5, Philosophy of Naturopathic Medicine.) Clients, who often use CAM for overall health and wellness,[22] expect to see positive results not only in objective disease parameters but also in general body functions (e.g., fatigue and energy, pain, inflammation, digestion, mental and emotional function) at a perceptible level. Thus, methods to assess the efficacy of the medicine should use holistic measures accounting for effects throughout the body systems and over the life cycle, if possible, and in an intervention's influence on social roles, productivity, and cost. Beyond the effectiveness of medicine for the individual patient, measures of an entire holistic practice may reasonably be expected to address public health as well as environmental, social, and economic outcomes.

Strides have been made in the development of measures that assess individual health globally.[24] There has been progress with the development and wide adoption of instruments, beginning with the Medical Outcomes Study SF-36 and its successors, and of measures such as "quality-adjusted years of life saved." However, there remains a lack of sensitivity to changes in disease at higher levels of function. The lack of sensitivity relates to the general absence of health measures (e.g., productivity) as opposed to disease measures in clinical trials. Gentle natural treatments may show smaller, more gradual improvements than may be expected from pharmaceutical and surgical interventions, and instruments sensitive to change are needed if trials are to be relatively short. Ultimately, the possibility of the superiority of natural health care in a few areas, such as longevity, the incidence of chronic disease in aging, and the incidence and prevalence of disease in progeny, ideally will require multidecade evaluation. Online tools available and in development for patient-reported outcomes hold potential for large, long-term studies with whole person measures.[24a]

Controls and Blinding

The choice of appropriate comparison controls is an important issue because every alteration of control answers different questions. The different questions in the comparison of a test intervention with placebo, a specific standard of care, usual care (the patient's baseline care), or time–attention behavior controls are all of interest. Sometimes ethical constraints may prevent a natural medicine therapy from being evaluated without a concomitant conventional therapy. Some cases of special interest are whether natural health care leads to lower overall morbidity and mortality (1) in patients who are randomly assigned to natural health care compared with those who are not; (2) in patients to whom it is equally available on the basis of cost and access compared with those to whom it is not; and (3) in patients who would actively pursue it in the presence of health system structural resistance (e.g., devoted consumers) compared with those who would choose it only if it were equally available or with those who would explore it only under special circumstances. The answers to these questions involve belief, motivation, cost, the restraint of use because of cost (from the consumer's side), the restraint of access because of cost (from the provider's side), and compliance. These answers may be fundamental to determining both the efficacy and efficiency of the inclusion of various forms of natural medicine in a rationally structured health care delivery system.

Treatments can be categorized simply into substances (drugs and remedies), procedures, and interactions (verbal and behavioral medicine). The double-blind RCT test system is easily applied with the evaluation of substances. Nonmaterial process interventions, such as manipulation, exercise, acupuncture, other forms of point work, and psychological and spiritual treatment, are more methodologically problematic in the RCT desideratum of blinding. Blinding is likely to prove difficult for most dietary manipulations, psychospiritual practices, and any whole practice intervention. In these cases, blinding often may be at least partially maintained by separating evaluation from treatment and blinding the evaluator. In considering the value of blinding, one should remember that studies that blind the practitioner and patient decrease or eliminate the possibility that intentionality will contribute to a positive outcome. However, CAM theories accommodate blinding and expectation as contributors to outcome.

Whole Practice Models

Given that individualized combinations of modalities and remedies generally are the rule in natural medicine and that their selection is guided by a health system's own principles and guidelines, evaluation of models of whole practices is most likely to reveal their potential health benefit. The main difficulty that arises is in attaining replicability of the intervention. (See Chapter 2, Functional Medicine, for a presentation of a methodology for systematizing individualization.) Although they remain both innovative and challenging, a number of intervention models are possible in approaching the ideal.

The simplest is a fixed combination of remedies, although this approach abandons individualization. If it is applied in trials with specific inclusion and exclusion criteria, however, the loss of individualization may be tolerable. A slightly more ambitious approach to whole practice is a menu of choices applied to several possible

etiologies in a symptom manifestation (disease) under study. As alternative medicines have been studied in recent years, pragmatic trials have been explored using a practitioner of given qualifications as the unit of intervention, treating the practitioner and his discipline as a "black box." A further step in sophistication is the intervention driven by guidelines or algorithms from the principles and body of knowledge of the discipline. Such guidelines may be derived through expert practitioner panels. The design and replicability of best practice protocols derived by experts from discipline principles are being studied in naturopathic[25] and Chinese medicines.[26] The complex models that have resulted may be facilitated operationally by manualization for the guidance of practitioners, who must be well trained to assess patients and deliver a standardized intervention flexibly.[27] A new question that would arise in such studies of manualized practice is the degree of adherence by the provider to the protocol. Another method is artificial intelligence programs that seek to emulate the decision-making processes of clinicians so that personalization can be standardized according to the algorithms practitioners use, often unconsciously.

The inability to distinguish the effects of single agents in pragmatic and whole practice studies frequently diminishes enthusiasm among grant review committees, since a whole practice is not easily transferable to other practitioners. However, whole practice studies are essential to determining the effectiveness and safety of natural medicine disciplines.

Observational Studies

There are essentially two components to medical research: observation and experimentation. Observation documents the natural history of clinical conditions, the approach to health, and the outcomes of treatment. In observational studies, ideas of association are formed and hypotheses are generated. Experimentation in medicine evaluates the outcomes while varying practice. Experimentation tests hypotheses generated in a variety of ways, including from observational study. In CAM, where many variants of health care of unknown safety and effectiveness are already in practice, observational study holds an important place. In medicine, research questions often involve pursuing a desired outcome by manipulating the input variables. The input variables are discovered ultimately through observation, as are the models in which to study them. Both observation and experimentation are needed to validly evaluate medical practices. With an appreciation for the appropriate place of observational study, we should not expect observational studies to provide the information nor meet the methods *desiderata* for experiments. In the relatively little examined practices of natural medicine and CAM, "until we know more about the practice, scope of practice, patient characteristics, utilization rates, and patient numbers, it is difficult to design appropriate studies or to even know which issues are worth studying."[6]

The challenge with results observed in evaluation of clinical practice is determining whether the observed association reflects a causative relationship. Although newer statistical tools, such as propensity scores and principal component analysis, may help, observational studies have been considered low on the hierarchy of validity in evaluation of medical practices. Effect sizes found in observational studies are often considered inflated, yet those from clinical trials and observational studies appear to be similar.[28,29]

Observational outcomes studies have some unique advantages in the study of natural medical practice. Outcomes research involves cohort studies wherein repeated health status evaluations in ordinary care settings compare outcomes of spontaneously arising variations of care, such as standard care and alternatives to it. Variations may be specific remedies, treatment approaches, or even whole professional practices. Advantages include the lack of ethical conflicts about withholding conventional treatment because the patients choose their practitioner. The effect of intention on the part of patient and practitioner is not abrogated. The medicine implemented is fully individualized with no constraint on the combinations considered best for a patient. The cost of research per case is a lesser constraint than in randomized trials if patients (or third parties) cover the cost of care. Costs can be included as an outcome. Mixed methods—quantitative and qualitative—in observational studies are usual and useful. More early observational studies will help to guide future trials. Best-case series, a retrospective review of selected cases, are having an effect on research directions in CAM.[30]

The care of patients currently using natural medicine is a valuable source of data for evaluating and monitoring care characteristics in different forms of practice. The growing coverage of CAM practitioners by third-party payers in health delivery systems over the past 20 years has generated much data on use and cost for currently licensed and insurance-covered natural medicine practitioners that can be used for comparison with outcomes of standard therapy.[31] The study by Cherkin et al,[32] designed on the model of the National Ambulatory Care survey, was remarkable in ascertaining the content of practice of state-licensed naturopaths, acupuncturists, chiropractors, and massage therapists.

The complexities of natural medicine (and any whole practice), with multiple inputs (patient characteristics and combination individualized treatments), broad measures, standardization data, and complex control conditions (e.g., "usual" care), both descriptive and analytical, all imply worthwhile data for exploration. For some CAM professions, the adoption of electronic medical records and the increased integration of CAM trained practitioners into conventional settings is generating rapidly growing databases in which clinical epidemiology may become common. To plan studies (including single-agent trials) and to understand results, the disciplines benefit from improving infrastructures for design, data collection, management, analysis, and interpretation. The NIH NCCAM has recognized the need and value of developing infrastructure at CAM institutions where there is clinical expertise in the practices.[33] There is a growing cadre of cross-trained and productive research CAM practitioners to engage in high priority studies with interdisciplinary expertise.

Basic Science Studies

Data from the basic sciences ensure the causal chain linking a happy clinical observation and an intervention. They help the wider community understand and use the natural medicine professions' experience. All of the natural medicine disciplines would benefit from greater exposure to the array of laboratory pharmacology and might, in turn, inform pharmacology of their own useful strategies. In the exploration of natural medical theory and in refining remedies, it would be useful to have access to a range of basic science techniques from analytical chemistry to classical microbiology to advanced molecular biology. Thousands of natural products have been screened for numerous laboratory outcomes. However, new understandings of human biology and advances in technology have made many more types of studies possible in areas such as combinatory pharmacodynamics, gene expression, proteomics, metabolomics, glycobiology, and immunology. Practitioners could guide the refinement of study questions from their best clinical judgment for future investigation.

One continuing need is in standardization of *materia medica*, not only on chemical constituents but also on biological activity. NIH NCCAM shows a sustained interest in funding the basic sciences in future CAM research centers.

Animal studies present their own complexities for the practices of interest. On one hand, acupuncture and homeopathic veterinary are common, and demonstration of the concepts of the animal study practices seems a reasonable route to improving practice. On the other hand, some CAM institutions have policies prohibiting animal research. Many vitalists and holistic practitioners hold that neither animal studies nor in vitro work appropriately reflects the human being. Their arguments may bear legitimate scrutiny. When animal work is the most fruitful way to pursue an important clinical goal, most natural medicine academic centers are willing to collaborate with animal laboratories.

Considering the salugenic rather than disease-oriented goals of most natural medicine practices, it may prove a valuable direction for natural medicine institutions to improve collective understanding through the basic science of normal and optimal physiology and the effects and mechanisms in which they are most likely to be expert. Alternative practitioners are well situated to contribute knowledge to the study of overall health, complexity in health care, and health behavior.

CRITERIA FOR A PRIORITIZED RESEARCH PROGRAM

The entire array of research design has a place in natural medicine research. There is a wide range of methodological discussion in publications and many currently ongoing studies spurred by substantial funding from the NIH. Methodologists have covered many problems in evaluation of different expressions of natural medicine, and the approaches and methods have been well summarized.[34] However, resources are always limited; therefore, research should be prioritized. Some major criteria to consider in developing programs of research to be considered are the following:

1. Focus on diseases with the highest burden of human suffering and the greatest public health significance as well as those in which standard therapy falls short of cure and effective management.
2. Evaluate first the treatments that have the greatest likelihood of reducing the burden of suffering—the low-hanging fruit among natural medicine therapeutics and preventives. Two sources for targeting decisions in this regard are the evidence already present in the scientific literature and the opinions and data of experienced natural medicine practitioners.
3. Attend to methodological evolution and the necessary sequencing of studies to achieve long range goals and to explore for and validate positive clinical experiences. Some research questions require methodological innovation because we do not yet know exactly how to answer them (e.g., in evaluating the whole-systems approach to disease, long-term safety, ultradilutional and combinatorial effects, spiritual practices, and even measures of overall health). Important questions may call for complex designs that combine observational and experimental research. Clinical research usually requires preclinical preparation. The confidence of investigators and funders and the clarity of their direction improve with preliminary pilot and observational data.
4. Attend to building a practice improvement and discovery infrastructure for the future in those practice disciplines prepared for it.

Over the past 50 years, tremendous progress has been made in the development of laboratory procedures for the diagnosis of disease. However, this work has focused primarily on pathologic processes—little has been done to help the physician recognize physiologic abnormalities before they progress to the pathologic stage. The problem is further aggravated for doctors of preventive/integrative/functional/natural medicine, who need to evaluate in an objective manner the nutritional status, lifestyle, physiology, toxic load, and health of their patients. The few widely available tests that exist tend to be oriented to measuring absolute values rather than functional indices and generally indicate abnormal values only after serious dysfunction develops.

We have compiled a number of useful assessments that we believe will greatly aid physicians who would like to utilize more objective tests in their evaluation of the pathophysiologic status of their patients. These are not meant to replace the standard, pathologically oriented, diagnostic procedures but rather to supplement them and aid in the early diagnosis of disease susceptibility and the quantification of the processes that usually precede clinical disease. Where possible, preference is given to tests that measure function rather than abstract absolute values. In keeping with the metabolic and scientific orientation of this textbook, emphasis has been placed on those procedures that have good support in the scientific literature for the evaluation of nutritional status.

Most of these laboratory procedures are on the cutting edge of our understanding of the assessment of the physiologic function of metabolically unique individuals. Because it is an emerging field, few experts exist and most are employed by the commercial laboratories performing and providing the procedures.

INTRODUCTION

Apoptosis is a distinct form of cell death controlled by an internally encoded suicide program. It is believed to occur in the majority of animal cells. It is a distinct event that triggers characteristic morphologic and biological changes in the cellular life cycle. It is common during embryogenesis, normal tissue and organ involution, and cytotoxic immunologic reactions, and occurs naturally at the end of the life span of differentiated cells. Apoptosis can also be induced in cells by the application of a number of different agents, including physiologic activators, heat shock, bacterial toxins, oncogenes, chemotherapeutic drugs, various toxic chemicals, ultraviolet and γ-radiation, and hypoxia. When apoptosis occurs, the nucleus and cytoplasm of the cell often fragment into membrane-bound apoptotic bodies, which are then phagocytized by neighboring cells. Alternatively, during necrosis, cell death occurs by direct injury to cells, resulting in cellular lysing and release of cytoplasmic components into the surrounding environment, often inducing an inflammatory response in the tissue. Apoptosis may occur in one cell, leaving surrounding cells unaffected, as opposed to necrosis, which affects multiple cells simultaneously.

A landmark of cellular self-destruction by apoptosis is the activation of nucleases and proteases that degrade the higher order chromatin structure of the DNA into fragments of 50 to 300 kilobases and subsequently into smaller DNA pieces of about 200 base-pairs in length. Activation of proteases, notably aspartate-specific cysteinyl proteases, referred to as caspases, is of primary relevance to apoptosis. Caspase-3 is considered to be the key mediator of apoptosis of mammalian cells, and its expression may be measured with immunohistochemical staining. Using fluorescent-labeled reagents, it is possible to tag the DNA break and identify the percentage of apoptotic cells with a high degree of accuracy.[1–6]

Measurable Features of Apoptosis

One of the most easily measured features of apoptotic cells is the breakup of the genomic DNA by cellular nucleases. These DNA fragments can be extracted from apoptotic cells and result in the appearance of DNA laddering when the DNA is analyzed by agarose gel electrophoresis. The DNA of nonapoptotic cells, which remains largely intact, does not display this laddering on agarose gels during electrophoresis. The large number of DNA fragments appearing in apoptotic cells results in a multitude of 3'-hydroxyl termini of DNA ends. This property can also be used to identify apoptotic cells by labeling the DNA breaks with fluorescent-tagged deoxyuridine triphosphate nucleotides. The enzyme terminal deoxynucleotidyl transferase catalyzes a template-independent addition of deoxyribonucleotide triphosphates to the 3'-hydroxyl ends of double- or single-stranded DNA. A substantial number of these sites are available in apoptotic cells, providing the basis for the single-step fluorescent labeling and flow cytometric method. Nonapoptotic cells do not incorporate significant amounts of the fluorescent-tagged deoxyuridine triphosphate nucleotides due to the lack of exposed 3'-hydroxyl DNA ends.

Apoptosis can also be characterized by changes in cell membrane structure. During apoptosis, the cell membrane's phospholipid asymmetry changes—phosphatidylserine is exposed on the outer membrane, whereas membrane integrity is maintained. Annexin V specifically binds phosphatidylserine, whereas propidium

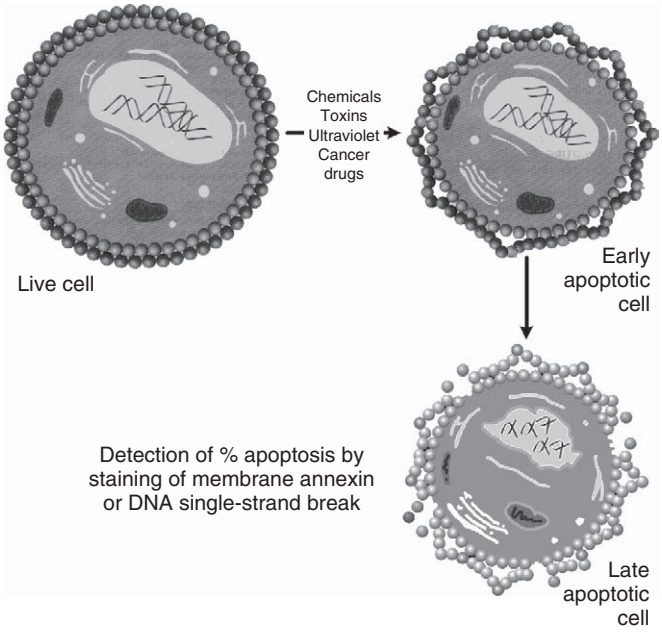

FIGURE 9-1 Detection of apoptosis using damaged membrane or DNA single-strand break and flow cytometry.

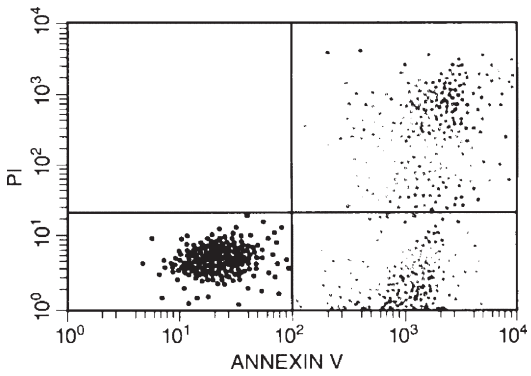

FIGURE 9-2 Separation of cells by flow cytometry and detection of apoptotic population.

iodide is a DNA-binding fluorochrome. When a cell population is exposed to both reagents, apoptotic cells stain positive for annexin V and negative for propidium iodide; necrotic cells stain positive for both, and live cells stain negative for both.[3]

This process of apoptosis and its analysis by flow cytometry are shown in Figures 9-1 and 9-2.

Another assessment of apoptosis involves ex vivo cell analysis. Specifically, the expression of active caspase-3 along with the Bcl-2/Bax ratio as markers of apoptosis can be measured. Immunohistochemical staining will reveal the expression of these apoptotic-related proteins, caspase-3 and cleaved caspase-3; the latter is indicative of apoptosis.[7] Bcl-2 is anti-apoptotic gene product that exists in ratio to Bax and Bak, which are pro-apoptotic gene products. This ratio is indicative of the degree of apoptosis, with a decreased Bcl-2:Bax ratio indicative of apoptosis. Cells from Bax (–/–) and Bak(–/–) knockout animals do not respond to apoptosis inducers. In these cells, cytochrome C is not released from the mitochondrial membrane to initiate the caspase cascade.[8] Thus, Bax and Bak are critical to apoptosis, and their expression in relation to Bcl-2 is highly correlative to apoptosis.

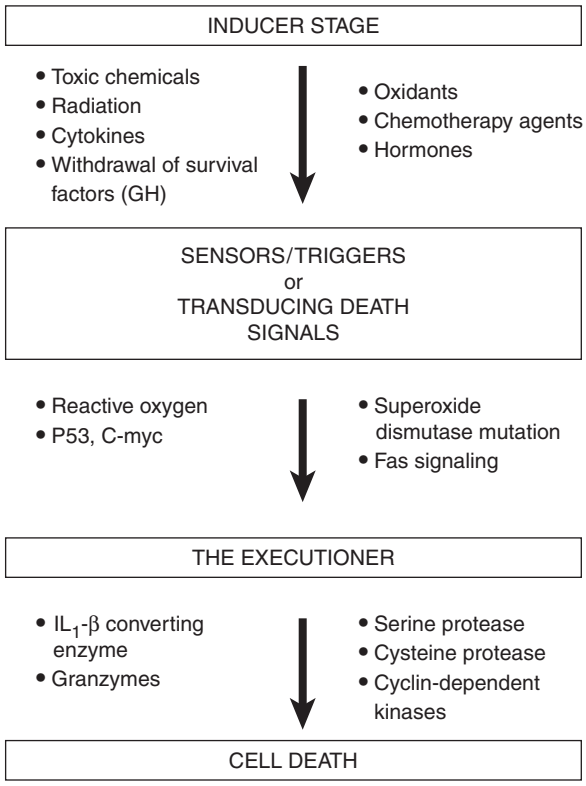

FIGURE 9-3 Various stages of "inside out" cell death or apoptosis.

Different Stages of Apoptosis

The process of apoptosis is divided into three different stages:
- Induction
- Sensing or triggering
- Execution

These stages of apoptosis are depicted in Figure 9-3. Induction represents the initial events that signal a cell so that apoptosis may begin. This induction phase may be induced by various physical agents, such as toxic chemicals, hypoxia, radiation, chemotherapy agents, hormones, and CD95 or Fas ligation. It has been proposed that the induction stage of apoptosis is prevented by many antioxidants (vitamin C, β-carotene, and vitamin E) and also by various biological response modifiers, including lentinan, thymic hormones, viral antigens, and cytokines.

The induction stage is followed by a decision on whether or not the cell will undergo apoptosis. The decision to die is under the control of a number of different pathways or cellular sensors that induce the apoptosis signal, which then triggers the central mechanisms. During this stage, enzymes such as interleukin1-β converting enzymes, serine protease, cysteine protease, granzymes, and cyclin-dependent kinases become activated. Once activated, these enzymes dismantle the cell and trigger the cell surface changes that cause direct cell recognition and engulfment of the dying cells by phagocytes. These central events are prevented by various antioxidants and biological response modifiers.

Apoptosis is Induced by Chemicals to Control Malignancy

Many chemicals have the capacity to bind to DNA, form DNA adducts, or cause DNA single-strand breaks, possibly leading to cancer. However, the body is equipped with many factors, enzymes, suppressor genes, and cellular sensors, all with the capacity to

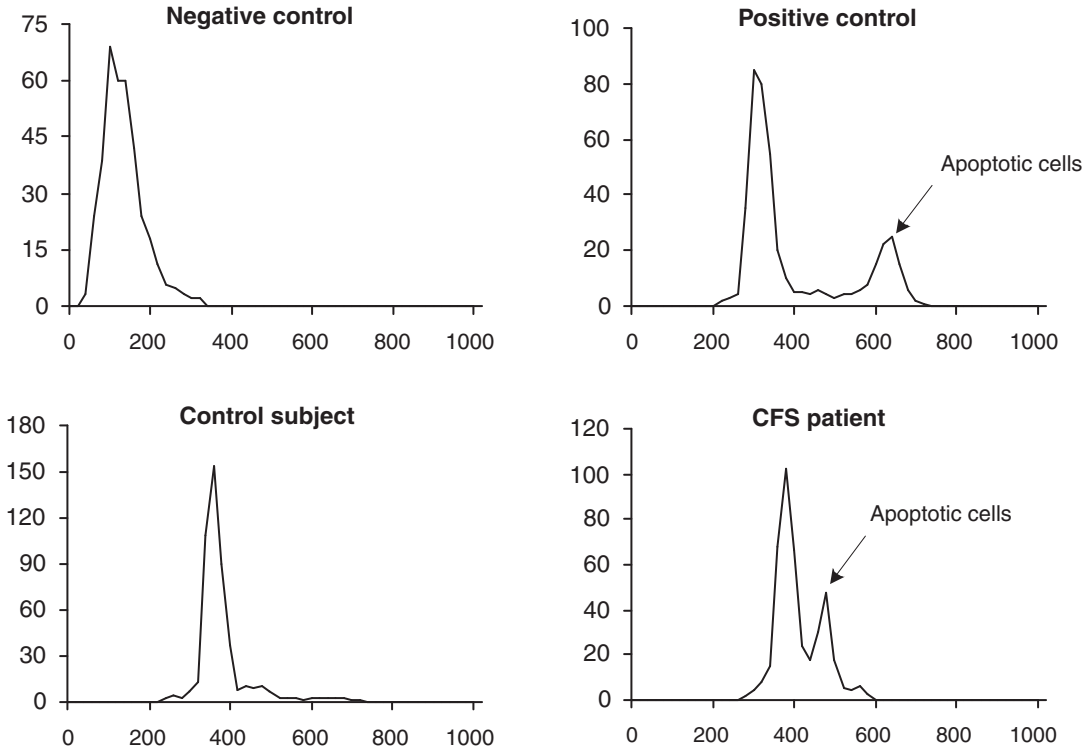

FIGURE 9-4 Enhanced apoptotic cell population in benzene-exposed individuals with chronic fatigue syndrome. Flow cytometry analysis of apoptotic cell population in negative control cells (HL-60 leukemic cell line), positive control cells (HL-60 leukemic cells treated with the Apogen camptothecin), control subjects, and benzene-exposed individuals. Peripheral blood leukocytes were isolated, cultured for 12 hours, fixed in paraformaldehyde, labeled with fluorescent-tagged deoxyuridine triphosphate nucleotides, and analyzed for apoptosis by flow cytometry.

prevent the consequences of this DNA damage by activating apoptosis-inducing signals.

The role of apoptosis in regulating tissue growth is readily apparent in the simple equation in which the rate of growth is equal to the difference between the rates of cell proliferation and cell death. Thus, tissues expand if the rate of proliferation exceeds the rate of cell death. This is one of the reasons for suggesting that defects in apoptosis may contribute to the transformed state.

An important prediction of the relevance of apoptosis to malignancy is that the rate of apoptosis versus mitosis should influence the behavior of a tumor. Recently, the relationship between the apoptotic and mitotic indexes in a tumor was demonstrated as predictive of outcome: a higher ratio of apoptosis to mitosis within the tumor correlated with positive prognosis. Further, it was found that this was not simply a function of cell death per se. Tumors with a high incidence of necrosis rather than apoptosis were correlated with poor prognosis. It therefore follows that treatments or conditions that favor apoptosis should have desirable effects, and that defects in the pathways leading to apoptosis are likely to play important roles in the process of oncogenesis.[4,5]

Many reactive chemicals and drugs such as acetaminophen, diquat, carbon tetrachloride, quinones, cyanide, polyhydroxyl polyether, methyl mercury, and organotin have been implicated in apoptosis (programmed cell death) and necrosis (toxic cell death).[9–16]

Most research on chemical induction of apoptosis is carried out with primary cultures of cell lines (e.g., neurons, thymocytes, carcinoma cells, leukemia cells, neuroblastoma, breast cancer cells, lymphoma); little has been published on the in vivo effects of chemicals on apoptotic cells in animal models and none in humans. Therefore, it was of interest to examine the effects of exposure to low levels of benzene, as well as through drinking water concentrations of up to 14 ppb on the apoptotic cell population, as well as to examine possible changes in the cell cycle progression.[9]

Evidence is sufficient for the carcinogenicity of benzene in humans; therefore, there is no safe level of exposure to this chemical or its metabolites. Published case reports, a case series, epidemiologic studies, and both cohort and case–control studies have shown statistically significant associations between leukemia and occupational exposure to benzene and benzene-containing solvents.[17,18]

It has been indicated that possibly 800,000 persons are exposed to benzene from coke oven emissions at levels less than 0.1 ppm, and 5 million may be exposed to benzene from petroleum refinery emissions at levels of 0.1 to 1 ppm. Since then, numerous chemicals have been implicated in apoptosis (or programmed cell death), which arises from damage to DNA. One of the authors, Vojdani along with collaborators, hypothesized that in individuals with a certain genetic makeup, benzene or its metabolites act as haptens, which may induce programmed cell death. The study involved a group of 60 male and female subjects who were exposed to benzene-contaminated water (at concentrations up to 14 ppm for a period of 3 to 5 years).[18a] For comparison, a control group consisting of 30 healthy males and females with a similar age distribution and without a history of exposure to benzene were recruited. Peripheral blood lymphocytes of both groups were tested for percentage of apoptotic cell population, using flow cytometry. When exposed individuals were compared with the control group, statistically significant differences between each mean group were detected (27.5 ± 2.4 and 10 ± 2.6, respectively), indicating an

increased rate of apoptosis in 86.6% of exposed individuals (P <0.0001; Mann-Whitney U-test). Flow cytometry analysis of apoptosis in a healthy control and a patient with chronic fatigue syndrome is shown in Figure 9-4.

It has been demonstrated that benzene induction of apoptosis is caused by a discrete block of the cell cycle progression.

There is a tendency for normal cells to commit "suicide" when deprived of usual growth factors or physical contact with their neighbors due to chemical exposure, which may represent a built-in defense against metastasis. Prompt activation of apoptosis in tumor cells that leave their native tissue presumably eliminates many metastatic cells before they have a chance to proliferate. In cancer, it is tumor cells that neglect to sacrifice themselves or forget to die. Researchers increasingly describe cancer as a disease involving both excessive proliferation of cells and abandonment of their ability to die. The dysregulation of apoptosis in malignant cells underlies both the initiation and progression of cancer.

Cancer develops after a cell accumulates mutations in several genes that control cell growth and survival. When a mutation seems irreparable, the affected cell usually kills itself rather than risk becoming deranged and potentially dangerous. However, if the cell does not die, it or its progeny may live long enough to accumulate mutations that enable it to divide uncontrollably and metastasize.

In many tumors, genetic damage apparently fails to induce apoptosis because the constituent cells have inactivated the gene that codes for the p53 protein. This protein can lead to activation of the cell's apoptotic machinery when DNA is injured by environmental agents, such as benzene or its metabolites. Therefore, it is important to study cell suicide in health and diseases.

CLINICAL APPLICATIONS

Apoptosis in Cancer

The failure of apoptosis in malignant cells in the context of irreparable DNA damage leads to tumor progression. Cancer therapies, namely, chemotherapy and radiation, control cancer by inflicting cell damage, which, in turn, triggers apoptosis. Unfortunately, >50% of all human cancers involve a mutation of p53, a central gene in apoptosis. p53 stimulates both the extrinsic death receptor pathway of apoptosis as well as the intrinsic mitochondrial pathway involving a decreased Bcl-2:Bax ratio. Thus, it is imperative to find therapies that promote apoptosis independent of p53. Promising therapies in this regard include curcumin,[19] derived from *Curcuma longa*, and resveratrol,[20] both of which are under investigative study for this application. Another promising cancer treatment involves the use of recombinant human apoptosis ligands to induce tumor necrosis factor-related apoptosis inducing ligand (TRAIL). These ligands induce apoptosis via TRAIL, a selective death receptor pathway in a broad range of cancer cell lines while sparing most normal cell types.[21]

The therapeutic potential for TRAIL inducing ligands is most promising in combination with cytotoxic chemotherapy agents. Advances in cancer therapy are likely to come in the arena of targeted therapies, the majority of which trigger specific receptor-driven pathways that culminate in apoptosis. The centrality of apoptosis induction in cancer cannot be overstated.

Apoptosis in Autoimmune Diseases

In cancer, it is the tumor cells that forget to die; in autoimmunity, immune cells fail to die when they are supposed to. Virtually all tissues harbor apoptotic cells at one time or another. Damaged cells usually commit suicide for the greater good of the body; when this does not occur, disease may develop. Autoimmunity occurs when the antigen receptors on immune cells recognize specific antigens on healthy cells and cause the cells bearing those particular substances to die. Autoimmune disease results from perpetuated immune-mediated tissue destruction, and can involve immune cells that are resistant to apoptosis. Under normal conditions, the body allows a certain number of self-reactive lymphocytes to circulate. These cells normally do little harm, but they can become overactive through several processes. For instance, if these reactive lymphocytes recognize some foreign antigen such as microbes on food and haptenic chemicals, then exposure to that antigen causes them to become excited. If, due to molecular mimicry, these antigens are similar to normal tissues, the activated cells may expand their numbers and attack the healthy tissue, thus causing an autoimmune disease.[1,22,23]

Autoimmune reactions usually are self-limited—they disappear when the antigens that originally set them off are cleared away. In some instances, however, the autoreactive lymphocytes survive longer than they should and continue to induce apoptosis in normal cells. Some evidence in animals and humans has indicated that extended survival of autoreactive cells is implicated in at least two chronic autoimmune syndromes—systemic lupus erythematosus and rheumatoid arthritis. In other words, the lymphocytes undergo too little apoptosis, with the result that normal cells undergo too much.[24,25]

Apoptosis During Viral Infection

Disturbance in the regulation of apoptosis is a component in various diseases. Viral illnesses are among the diseases caused by apoptosis dysregulation. After entering a cell, viruses attempt to shut down the cell's ability to make any proteins except those needed to produce more virus. This act of stalling host protein synthesis is enough to induce many kinds of cells to undergo apoptosis. If the host cell dies, the virus is also eliminated. Therefore, certain viruses have evolved ways to inhibit apoptosis in the cells they infect.

Epstein-Barr virus, which causes mononucleosis and has been linked to lymphomas in humans, uses a mechanism that has been seen in other viruses. Epstein-Barr virus produces substances that inhibit apoptosis. Papillomavirus, a major cause of cervical cancer, inactivates p53, a central mediator of apoptosis. Cowpox virus, a relative of which is used as the smallpox vaccine, is another virus that inhibits caspase activation and attendant apoptosis. Investigators interested in antiviral therapy are now exploring ways to block the activity of the antiapoptotic molecules manufactured by viruses.[24]

Apoptosis in Acquired Immunodeficiency Syndrome

Induction of apoptosis by viruses in healthy cells is believed to contribute to the immune deficiency found in patients with acquired immunodeficiency syndrome (AIDS). In these patients, infection with human immunodeficiency virus (HIV) causes T-helper cells to die. As T-helper cells gradually disappear, cytotoxic cells, such as natural killer cells, perish as well through apoptosis, because they cannot survive without the growth signals produced by T-helper cells. When the number of T cells dwindles, so does the body's ability to fight infections, especially viral and parasitic infections. Researchers have shown that many more helper cells succumb in addition to those that are infected with HIV. It is also highly probable that a large number of the cells die through apoptosis. Apparently, Fas plays a crucial role in this process.

Normally, T cells make functional Fas only after they have been active for a few days and are ready to die. However, helper cells from AIDS patients may display high amounts of functional Fas even before the cells have encountered an antigen. This display of Fas would be expected to cause the cells to undergo apoptosis prematurely whenever they encounter Fas ligand on other cells (such as on T cells already activated against HIV or other microbes). In addition, if the primed cells encounter the antigen recognized by their receptors, they may trigger their own death.

It is also possible that oxygen-free radicals trigger the suicide of virus-free T cells. These highly reactive substances are produced by inflammatory cells drawn to infected lymph nodes in HIV patients. Free radicals can damage DNA and membranes in cells. They will cause necrosis if they do extensive damage, but they can induce apoptosis if the damage is more subtle. In support of the free-radical theory, researchers have found that molecules capable of neutralizing free radicals prevent apoptosis in T cells obtained from AIDS patients.[24,25]

Therapies with antiapoptotic medication, such as Trolox, a water-soluble analog of vitamin E that prevents oxidative stress, and pyrrolidine dithiocarbamate, a potent inhibitor of nuclear factor-κB, are now the focus of AIDS and autoimmune disease studies.[26,27]

Additionally, protease inhibitors, which are the mainstay of HIV therapy, inhibit apoptosis in immune cells.[28]

The mechanism underlying the apoptosis inhibition is as of yet unknown, but interestingly, supratherapeutic doses of protease inhibitors have an opposite, pro-apoptotic, effect.

Apoptosis in the Heart and Brain

In contrast to cancer, where cells forget to die and insufficient apoptosis occurs, excessive apoptosis accounts for much of the cell death that follows heart attacks and strokes. In the heart, vessel blockage decimates cells that were fully dependent on the vessel. Those cells die by necrosis, partly because they are catastrophically starved of the oxygen and glucose they need to maintain themselves and partly because calcium ions, which are normally pumped out of the cell, rise to toxic levels.

Over the course of a few days, cells surrounding the dead zone, which initially survive because they continue to receive nourishment from other blood vessels, can die as well. Later, however, many cells die by necrosis after being overwhelmed by the destructive free radicals that are released when inflammatory cells swarm into the dead zone to remove necrotic tissue. The less injured cells commit suicide by apoptosis.

If the patient is treated by restoring blood flow, still more cells may die by necrosis or apoptosis because reperfusion leads to a transient increase in the production of free radicals. Similarly, in strokes due to inflammation, release of such neurotransmitters as glutamate lead to necrosis and apoptosis. Understanding of the factors that lead to the tissue death accompanying heart attack, stroke, and reperfusion has led to new ideas for treatment. Notably, cell death might be limited by drugs and other agents that block free-radical production or inhibit proteases.

Apoptosis also accounts for much of the pathology seen in such diseases as Alzheimer's, Parkinson's, Huntington's, and amyotrophic lateral sclerosis (Lou Gehrig's disease), which are marked by the loss of brain neurons. Elevated apoptosis in these neurologic diseases seems to be related to lack of production of the nerve growth factor and to free radical damage. It seems likely that a combination of such factors could cause many cells to destroy themselves. Manipulation of this process of cell killing may help in treating these neurologic diseases. Studies in animal models imply that long-term delivery of nerve growth factors could protect against programmed cell death in these conditions. Therefore, a greater understanding of the mechanisms involved in cell death should greatly enhance those important steps.[22,26,29]

CONCLUSIONS

Apoptosis and cell proliferation play an important role in development, differentiation, homeostasis, and aging.[2–6] The balance established between these two processes depends on various growth and death signals that are influenced by diet, nutrition, lifestyle, and other environmental factors. When the equilibrium between life and death is disrupted by aberrant signals (e.g., low levels of antioxidants in the blood or tissue cells), either tissue growth or atrophy occurs.

Under normal conditions with optimal nutritional factors, tissue homeostasis is sustained by balancing the effects of mitosis and apoptosis. The importance of this balance can clearly be seen when one of these processes becomes predominant (Figure 9-5). The apoptotic potential within each cell is critical for the health of the host. Apoptosis is an elegant response to overwhelming DNA damaging stress. This seemingly heroic sacrifice of self for the greater good underpins healthy living. Imbalance of apoptosis regulators, genetic mutations, and viral infections thwarts the healing impact of apoptosis. Finding ways to restore apoptotic balance is critical to health.

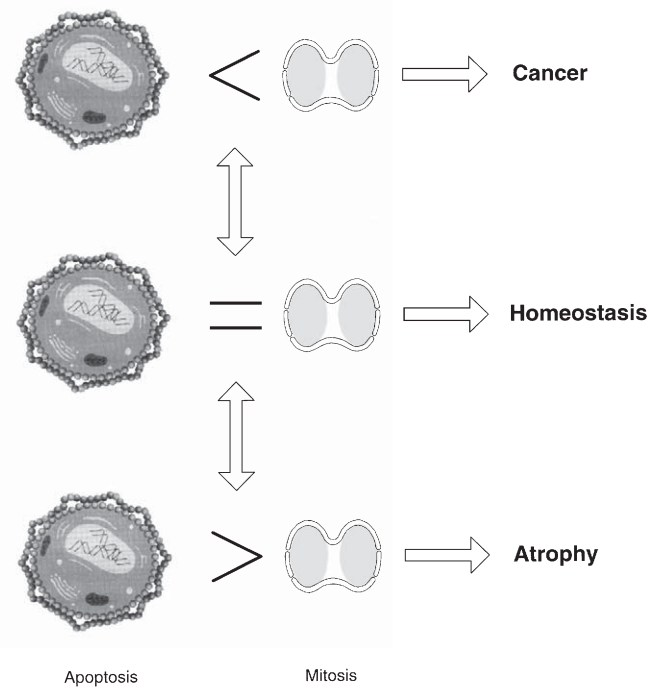

FIGURE 9-5 Balance or imbalance between the rate of apoptosis and mitosis determines tissue homeostasis, atrophy, cell proliferation, and development of cancer.

INTRODUCTION

Small intestinal bacterial overgrowth (SIBO) is an abnormal colonization within the small bowel by bacteria normally found in the colon, mouth, or pharynx.[1] Also called bacterial overgrowth of the small intestine (BOSI), "blind-loop," or "stagnant loop,"[2] SIBO is a potentially serious disorder that leads to problems such as malabsorption, anemia and weight loss, malnutrition,[3] increased intestinal permeability, and bone loss.[4] Breath testing for hydrogen (H_2) and methane (CH_4) provides a simple noninvasive means of detecting SIBO. Once SIBO has been identified, antimicrobials are typically administered to eradicate the bacteria. Subsequent attention to underlying causes is also essential in preventing recurrence.

Frequency of Small Intestinal Bacterial Overgrowth

Bacterial overgrowth of the small intestine is an overlooked contributing factor in several common disorders.[5] Several studies, for example, demonstrated the presence of SIBO in patients with irritable bowel syndrome (IBS).[6] In one such study, in which 84% of IBS patients tested positive for SIBO (vs 20% of healthy controls), successful eradication of SIBO led to a 75% improvement (compared with a 36.7% improvement in those with incomplete eradication, and an 11% improvement in participants receiving placebo).[7] SIBO has also been observed in patients with chronic fatigue syndrome[8] and/or fibromyalgia.[9] SIBO tends to increase intestinal permeability (aka "leaky gut").[10] Investigators who found leaky gut in 37.5% of patients with fibromyalgia suggested exposure of immune cells to luminal antigens and consequent immune modulation as a likely mechanism for the pain syndrome.[11] A variety of anatomic and motor disorders of the small bowel can lead to SIBO, including surgical loops, diverticula, strictures, adhesions, tumors, fistulas,[2] scleroderma,[12] intestinal pseudoobstruction,[13] and diabetic enteropathy.[14] Jejunal diverticulosis[5] and Crohn's disease[15] have both been associated with SIBO, particularly in patients with previous intestinal surgery. Although the concentration of bacteria normally increases exponentially toward the distal end of the small intestine,[2] far fewer bacteria inhabit the small intestine than the colon.[16] A common feature of most of these disorders is stasis of small bowel contents, which allows bacterial concentrations to increasingly resemble those of the large intestine (Box 10-1).[16,17] Although many of the bacteria found in SIBO are beneficial within the colon, these same microorganisms can have deleterious effects within the delicate environment of the small intestine.

Interestingly, many patients with celiac disease whose symptoms persist despite a gluten-free diet have been shown to have SIBO, with improvement only after bacterial eradication.[18] The incidence of SIBO also increases with age.[19] It has been found that 64% of individuals more than 75 years of age with chronic diarrhea have colonic-type flora in their small bowels[5] and that SIBO is the most common cause of clinically significant malabsorption in elderly persons.[2]

Pathophysiology

Two major factors control the numbers and types of bacteria within the small bowel: intestinal peristalsis and gastric acid secretion.[2,16] Accordingly, SIBO has been associated with both intestinal stasis and hypochlorhydria.[17] Other factors that influence SIBO include pancreatic enzyme secretion,[20] disaccharidase production by

BOX 10-1 Causes of Small Intestinal Bacterial Overgrowth

- Achlorhydria, hypochlorhydria, drug-induced hypoacidity
- Chronic constipation
- Stasis resulting from structural changes (e.g., diverticulosis, blind loops, radiation damage, stricture, fistulas, intestinal pseudoobstruction, adhesions resulting from prior surgery)
- Chronic pancreatic insufficiency
- Disaccharidase deficiencies (lactase)
- Damaged ileocecal valve
- Immunodeficiency (especially of secretory immunoglobulin A)
- Diabetes mellitus
- Scleroderma
- Crohn's disease

BOX 10-2 When to Consider Breath Testing for Small Intestinal Bacterial Overgrowth

- Gas, bloating, or diarrhea, usually after eating
- Unexplained weight loss
- Evidence of malabsorption
- Chronic hypochlorhydria or achlorhydria
- Use of acid-blocking medications
- Prior intestinal surgery, chronic constipation, or other causes of intestinal stasis
- Intolerance of disaccharides (lactose)
- Unexplained vitamin B_{12} deficiency, weight loss, or bone loss
- Unexplained nutrient insufficiencies (e.g., calcium, magnesium, fat-soluble vitamins)
- Elevations of fecal short chain fatty acids
- Unexplained "leaky gut"

BOX 10-3 Signs and Symptoms of Bacterial Overgrowth

- Gas, bloating, and flatulence
- Diarrhea
- Abdominal cramping
- Steatorrhea
- Lactose intolerance
- Megaloblastic anemia

microvilli,[21] ileocecal valve function,[22] bile salts, luminal pH, and oxidation-reduction potential.[16]

For SIBO to produce clinical consequences, an adequate concentration of organisms with particular metabolic properties within specific locations of the small intestine is required. For example, a heavy concentration of strict anaerobes and coliforms in the proximal small intestine is more likely to be associated with malabsorption than a flora consisting of fewer strict anaerobes or coliforms or when strict anaerobes or coliforms are located in the distal small intestine.[16] For this reason, SIBO may be asymptomatic in some individuals yet produce signs and symptoms in others. Box 10-2 outlines clinical signs and symptoms that alert the practitioner to consider testing for SIBO.

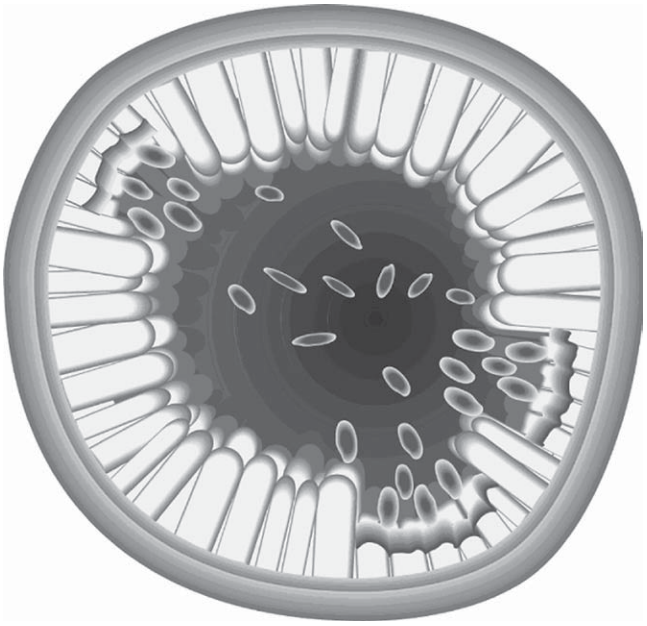

FIGURE 10-1 In small intestinal bacterial overgrowth, free bile acids can damage the brush border, resulting in reduced enzyme activity and maldigestion. (Courtesy Genova Diagnostics, Asheville, NC.)

Diagnosis

Signs and Symptoms

The classic SIBO syndrome is characterized by megaloblastic anemia resulting from vitamin B_{12} deficiency and weight loss and diarrhea secondary to fat malabsorption.[16] However, many patients present with nonspecific symptoms 1 to 2 hours after a meal, including bloating, flatulence, and abdominal pain resulting from bacterial fermentation of intraluminal sugars and associated gas production (Box 10-3).[8,18]

Via secretory and osmotic processes, diarrhea may occur even in the absence of significant steatorrhea. Unabsorbed fats and bile salts are modified by bacteria in the colon to hydroxylated fats and free bile acids, respectively, which stimulate colonic secretion of water and electrolytes.[16]

Bile salts, essential to fat emulsification and assimilation, must be conjugated with taurine or glycine to function properly. In SIBO, bacteria in the proximal small intestine deconjugate bile salts to form free bile acids.[16] This can have two major clinical repercussions: (1) free bile acids can promote mucosal damage (Figure 10-1), resulting in reduced brush-border enzyme activities (especially lactase),[23] defects in mucosal uptake of sugars and amino acids, enteric blood loss, and protein-losing enteropathy; or (2) the conjugated bile salt concentration may fall below the

concentration necessary for effective micelle formation, resulting in fat malabsorption, steatorrhea,[16,17] and deficiencies of fat-soluble vitamins.[3]

Fat malabsorption in SIBO can also result from mechanical interference, specifically formation of a pseudomembrane, thought to represent a maladaptive defense mechanism against the bacterial overgrowth.[24]

Unabsorbed fatty acids can form insoluble soaps with calcium and magnesium, rendering them unavailable.[3] Osteomalacia, night blindness, hypocalcemic tetany,[2] or metabolic bone disease[4] may develop as a consequence of lipid malabsorption in patients with SIBO. Although rare, iron deficiency anemia may result from blood loss.[3]

SIBO may also lead to vitamin B_{12} deficiency, with megaloblastic anemia and low serum cobalamin levels.[2,16] Although intrinsic factor is not altered by anaerobic bacteria, microbes are capable of detaching vitamin B_{12} from the intrinsic factor, as well as directly using B_{12}.[22] Either mechanism has the effect of making the vitamin unavailable. Paradoxically, serum folate values are usually normal or even elevated in SIBO, a result of bacterial synthesis of the vitamin.[25]

Hypoproteinemia may also occur in SIBO, secondary to protein-losing enteropathy and protein malabsorption.[3,17] In addition, bacteria may metabolize proteins to ammonia and fatty acids, thereby rendering them unavailable to the host.[23]

LABORATORY ASSESSMENT

The composition of bacterial populations contaminating the small bowel is complex and variable.[2] However, the diagnosis of SIBO tends to be oriented less to the identification of specific microorganisms and more to overall bacterial concentrations.[2]

Endoscopy

Culture of a small bowel aspirate via endoscopy is a direct method for diagnosing SIBO; abnormally high bacterial counts confirm the diagnosis.[17] This method offers good sensitivity but low specificity. Because the aspirate is typically taken from only one location, SIBO in the more distal end of the small bowel or concentrated in a large diverticulum or blind loop may be missed.[26] Intubation methods are invasive, time consuming, uncomfortable, and expensive.

Breath Testing

Breath tests were devised as less invasive alternatives to intubation and culture, offering greater patient comfort and convenience. They also offer good sensitivity[27]; a meta-analysis suggested that lactulose breath testing identifies SIBO in approximately 54% of IBS patients compared with only 4% of patients via jejunal aspirate and culture.[28]

Breath tests are based on the ability of intestinal microbes to ferment carbohydrates, producing H_2 or CH_4 in the process. A fraction of these gases naturally diffuse from the bowel to the circulation and are excreted with expired air. Because there is no other metabolic source of H_2 and CH_4, pulmonary excretion of these gases is used as a measure of bacterial fermentation during the passage through the bowel.[29]

A lactulose breath test is commonly employed to diagnose SIBO. Typically, patients ingest a challenge dose of lactulose (a synthetic, nonabsorbed disaccharide) after two days of fiber restriction and a 12-hour fast.[30] Glucose has also been used as a challenge agent, although its rapid absorption reduces the test's sensitivity in the distal ileum[27] and the agent is not suitable for patients with blood sugar disorders such as diabetes. In all cases, intestinal bacteria modify the challenge substance, producing an early peak in breath gas values in patients with SIBO. In the case of lactulose, which offers the advantage of traveling the full length of the small intestine, the early H_2 and CH_4 peak is typically followed by a prolonged peak representing colonic bacterial activity (approximately 90 minutes into the collection process).[27,31]

In the lactulose breath test, breath specimens are collected by exhaling into a special mouthpiece connected to a vacuum-sealed collection tube. A fasting (prechallenge) breath sample is collected, 10 g of lactulose are ingested, and then five more breath specimens are collected at timed intervals over a 2-hour period. Breath levels of H_2 and CH_4 are plotted over time; earlier rises in breath gas values correlate with more proximal portions of the small intestine.

Hydrogen Versus Methane

Many studies using carbohydrate challenges have measured only breath H_2. However, 30% to 50% of H_2 producers also produce CH_4,[32] most likely a result of "methanogenic" bacteria, which consume H_2, producing CH_4 in the process.[30] Individuals whose intestines harbor methanogenic bacteria typically produce greater amounts of breath CH_4 during the test, thus being potentially missed on a test examining only H_2.[33]

Clinical correlations have been noted between various disorders and the production of H_2 versus CH_4. In one study, individuals producing higher amounts of H_2 relative to CH_4 reported significantly increased bloating and cramping after carbohydrate ingestion, whereas individuals producing high CH_4 reported no significant increase in these symptoms.[34] Specific IBS symptoms also vary with breath gas values. For example, CH_4 production has been associated with constipation-predominant IBS, whereas H_2 production has been associated with diarrhea.[35] SIBO, in general, appears to be more common in diarrhea-predominant IBS than in constipation-predominant IBS.[28]

Interpretation

Lactulose is normally not fermented until it reaches the colon. As a result, the typical fasting breath sample contains less than 20 ppm of H_2 or CH_4. An increase in breath gas levels in the later breath specimens (90 and 120 minutes) usually reflects colonic bacterial fermentation and is considered normal. Lack of the expected colonic peak can result from antibiotics or an acidic colonic pH.[36,37] In patients with SIBO, the lactulose is fermented in the small intestine, resulting in an early peak in breath gas values.[27]

A positive test result (indicating SIBO) is defined by either (1) the presence of a total H_2 and CH_4 gas peak more than 15 ppm above baseline levels, occurring less than 90 minutes after lactulose ingestion, or (2) an elevated baseline (fasting) breath gas concentration, even if there is no large increase from baseline over the next few samples.[38] Elevated baseline values occur in up to one-third of patients with SIBO[36] and are thought to relate to the fermentation of endogenous brush-border glycoproteins.[39]

False-Positive and False-Negative Results

Various factors may interfere with the breath test, resulting in false-negative or false-positive results. Detailed instructions for breath collection help to minimize this interference.

False-Positive Results. The following factors may account for a false-positive result on a breath test:

- Failure to fast for at least 12 hours before the test or to avoid dietary fiber the day before collection can result in excessive "background noise" that contributes to the overall concentration of breath gases.[29]

- Sleeping, smoking, or eating shortly before or during sample collection can increase concentrations of breath gases.[40]
- Fermentation by oropharyngeal flora can lead to early, transient elevations in breath gases after carbohydrate ingestion.[41] As a result, teeth and tongue brushing before specimen collection is recommended.

False-Negative Results. False-positive results on a breath test can be caused by the following factors:

- Diarrhea or the recent administration of antimicrobials can temporarily reduce the concentration of gut bacteria,[42] thus obscuring SIBO. Laxatives and enemas pose a similar risk.[43] Patients are advised to wait at least 1 week after antibiotic therapy before performing the test.
- SIBO confined to the distal ileum may go undetected if the breath gas peak produced in the ileum merges with the breath gases produced by the colonic flora.[27]
- Rapid intestinal transit may cause delayed increases in breath gases, leading to a rise only after the lactulose has already reached the cecum.[44] This is particularly relevant for patients with SIBO who have undergone small bowel resection.

TREATMENT OF BACTERIAL OVERGROWTH

Bacterial Eradication

Unfortunately, addressing only the contributing factors to SIBO usually fails to reverse it; therefore, the primary treatment of SIBO is directed at altering the intestinal flora with antimicrobials.[17] Conversely, investigation and treatment of the root cause is necessary to prevent chronic recurrence of SIBO.

Most patients with clinically significant SIBO host an intestinal flora consisting largely of anaerobes; however, some patients harbor a predominance of gram-negative aerobes, such as *Escherichia coli*, *Klebsiella*, and *Pseudomonas*.[45] As a result, the most effective antimicrobial agent is one targeting both aerobic and anaerobic microorganisms.[2]

Antibiotics

The first-line antibiotic for SIBO has been tetracycline (250 mg four times daily for 7 days).[2] However, the high prevalence of bacterial resistance to this drug (up to 60% of patients with SIBO)[2] has led to the use of alternative antibiotics. Common alternatives include the quinolones, amoxicillin with clavulanic acid (Augmentin), clindamycin, and metronidazole.[46,47] Although included in some of these lists, antibiotics with poor activity against anaerobes might best be avoided in the treatment of SIBO (e.g., penicillin, ampicillin, and the oral aminoglycosides kanamycin and neomycin).[2]

The minimally absorbed antibiotic, rifaximin, is particularly effective while also minimizing the risk of side effects. In one study, a 7-day course of rifaximin (Xifarxan) at 400 mg three times daily normalized breath hydrogen excretion in 70% of patients with SIBO, whereas tetracycline normalized H_2 excretion in only 27% of patients.[48] More recent studies of rifaximin utilized 550 mg twice daily for 14 days and demonstrated equivalent resolution of SIBO, as well as elimination of IBS symptoms.[49]

A poor response to antibiotics may indicate mucosal disease, antibiotic resistance, antibiotic-associated diarrhea, or an incorrect diagnosis.[22,50] Recurrence of symptoms after treatment suggests the need for follow-up testing and possible re-treatment. Older age, history of appendectomy, and chronic use of proton pump inhibitors increase the likelihood of recurrence.[51] Because prolonged antibiotic therapy significantly raises the risk of diarrhea, *Clostridium difficile* infection, and bacterial resistance,[2] the administration of probiotics is advised to minimize such side effects.[21]

Antibiotic Alternatives

Peppermint oil, which has been used successfully in patients with IBS, is a volatile oil with antimicrobial properties.[52] Enteric-coated peppermint oil (dose of 0.2 mL three times a day) dramatically reduced gastrointestinal symptoms in a patient with SIBO.[53] Follow-up breath testing suggested some persistent bacterial overgrowth; the addition of an established antimicrobial agent such as berberine might help improve the results.[54] Further research on the use of botanical agents in SIBO is clearly needed.

A small double-blind study examined the effect of oral probiotics (combined *Lactobacillus acidophilus* and *L. casei* strains) on SIBO. A significant decrease in breath H_2 concentration was noted as early as 1 week into treatment, providing evidence that *Lactobacillus* strains might be useful in SIBO.[55]

Addressing the Underlying Cause

Bacterial overgrowth of the small intestine may easily recur if root causes are not addressed.

Restoration of Gastric Acidity

Because gastric acidity is a critical deterrent to SIBO, restoration of normal stomach pH in patients with hypochlorhydria or achlorhydria is essential. This may include the use of betaine hydrochloride with meals or the discontinuation of antacid medications. SIBO has been found in both healthy subjects and patients with an ulcer after even short-term (5-week) administration of omeprazole.[56] Alterations in gastric pH affect digestive capacity, leading to incompletely digested proteins providing substrate for bacteria in the terminal ileum.

Normalization of Intestinal Motility

As mentioned, intestinal stasis is another major contributing factor to SIBO. When not resulting from anatomic or organic causes, reduced motility may be improved with measures such as increased dietary fiber, water, probiotics, stress management, and exercise. Surgical correction of anatomic causes of intestinal stasis, such as small bowel diverticula, may be warranted.[57]

Supportive Measures

SIBO patients may become lactose intolerant as a result of disaccharidase deficiency. This is often ameliorated with bacterial eradication[58]; however, temporary avoidance of all disaccharides can also help to "starve" the excess bacteria and allow healing of the intestinal lining.[59]

Substituting more easily absorbed medium-chain triglycerides for most dietary fat may be helpful in patients with diarrhea and steatorrhea.[2]

Probiotics and prebiotics are recommended to help restore normal balance of intestinal flora, especially in patients with a history of antibiotic use.[21,55]

INTRODUCTION

Signaling pathways in normal cells consist of growth and controlling messages from the outer surface deep into the nucleus. In the nucleus, the cell cycle clock collects different messages, which are used to determine when the cell should divide. Cancer cells often proliferate excessively because genetic mutations cause induction of stimulatory pathways and issue too many "go ahead" signals, or the inhibitory pathways can no longer control the stimulatory pathways.[1]

Over the past 5 years, impressive evidence has been gathered with regard to the destination of stimulatory and inhibitory pathways in the cell. These pathways converge on a molecular apparatus in the cell nucleus that is often referred to as the *cell cycle clock.* The clock is the executive decision maker of the cell; apparently, it runs amok in virtually all types of human cancer. In a normal cell, the clock integrates the mixture of growth-regulating signals received by the cell and decides whether the cell should pass through its life cycle. If the answer is positive, the clock leads the process.

THE CELL CYCLE

A scheme of the classic cell cycle is shown in Figure 11-1. The cell cycle compartments are drawn such that their horizontal position reflects their respective DNA content. Cells that contain only one complement of DNA from each parent (2C) are referred to as *diploid cells.* Cells that have duplicated their genome, and thus have 4C amounts of DNA, are called *tetraploid cells.*

The cell cycle is classically divided into the following phases:

- G_0
- G_1
- S
- G_2
- M

The cell cycle phase of G_1 was historically considered to be a time when diploid (2C) cells had little observable activity. Because this time precedes DNA synthesis, the term *Gap 1 (G_1)* was coined. It is known that there is quite a bit of transcription and protein synthesis during this phase. At a certain point in the cell's life, the DNA synthetic machinery turns on. This phase of the cell's life is labeled *S* for synthesis. As the cell proceeds through this phase, its DNA content increases from 2C to 4C. At the end of S, the cell duplicates its genome and now is in the tetraploid state. After the S phase, the cell again enters a phase that was historically thought to be quiescent. Because this phase is the second gap region, it is referred to as *G_2.* In the G_2 phase, the cell produces the necessary proteins that play a major role in cytokinesis. After a highly variable amount of time, the cell enters mitosis (*M*). DNA content remains constant at 4C until the cell actually divides at the end of telophase.

The enlarged parent cell finally reaches the point where it divides in half to produce its two daughters, each of which is endowed with a complete set of chromosomes. The new daughter cells immediately enter G_1 and may go through the full cycle again. Alternatively, they may stop cycling temporarily or permanently.[2–4] Telomeres, condensed chromatin caps on the ends of chromosomes, dictate the ultimate number of cell divisions that can occur. With each cell division, the telomeres shorten, ultimately to the point that disallows further mitosis. Thus, telomeres are

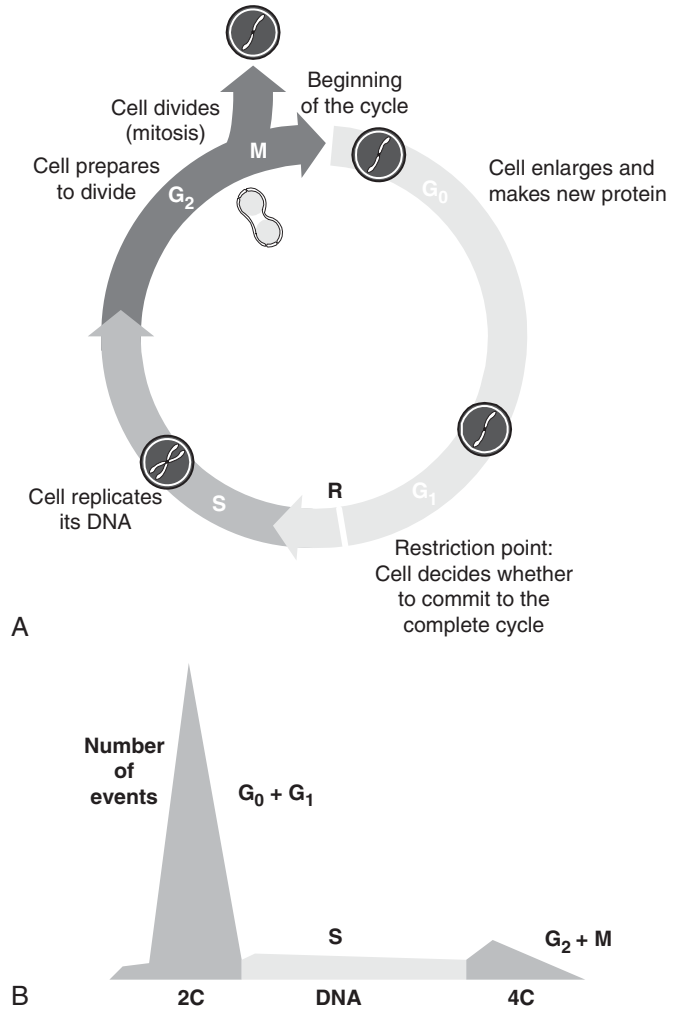

FIGURE 11-1 Stages of cell cycle (G_0, G_1, S, G_2, and M phases) (A) and DNA histogram (B) generated by flow cytometry.

considered to be the "mitotic clock." Telomere shortening is linked to aging, age-associated diseases, including cancer, coronary artery disease, and heart failure. Cell proliferation capacity, the cellular environment, and epigenetic factors affect telomere length and therefore cells' mitotic capacity.

Telomere length can be assessed and is available as a clinical test. The telomere length is reported as a telomere score, which is a calculation of the telomere length derived from nucleated white blood cells. This result is then compared with the average telomere length of similar aged sample population. This information can be utilized to prioritize interventions that increase telomere length, such as dietary, stress reduction, antioxidant, and vitamin therapies.[5]

Another influence on the cell cycle clock is circadian rhythms, or circadian clock. The circadian clock is the result of molecular clocks in each cell, circadian physiology, and ultimately, the suprachiasmatic nuclei in the hypothalamus. The circadian clock regulates the activity and expression of cell cycle check point related proteins and, in turn, these check points regulate circadian clock proteins. This has significant clinical implications, particularly in the area of cancer treatment. Both the toxicity and efficacy of cytotoxic agents can vary by more than 50% as a function of when they are dosed in experimental models.[6] The administration of cytotoxic agents in accordance with the circadian induced activity of the target cells is gaining ground as a reasonable therapeutic approach.

FLOW CYTOMETRY TO ASSESS CELL CYCLE STATUS

Flow cytometry is a method of measuring cell properties as they "flow" through a detector while being illuminated with intense light. Tissues are generally disaggregated into single-cell suspensions and stained with one or more fluorescent dyes. The cells are forced to flow within a sheath of fluid, eventually being intersected and interrogated by an intense light source, such as a laser beam. As the cell enters the laser beam, it scatters light in all directions. The measurement of light scattered in the forward direction yields information on the particle's size. Scattered light at right angles to the incident light beam provides information on the internal granularity of the cell. If the cell has been stained with one or more fluorescent dyes, a correlated measurement of more than one cellular parameter can be achieved.

CLINICAL APPLICATION

Patients Exposed to Carcinogenic Chemicals and Patients with Chronic Fatigue Syndrome

To determine whether peripheral blood lymphocytes (PBLs) isolated from individuals with chronic fatigue syndrome (CFS) and chemically exposed patients represent a discrete block in cell cycle progression, PBLs isolated from CFS and control individuals were cultured, harvested, fixed, stained with propidium iodide, and analyzed by flow cytometry. The nonapoptotic cell population in PBL isolated from CFS individuals consisted of cells arrested in the late S and G_2/M boundaries, compared with healthy controls. The arrest was characterized by increased S and G_2/M phases of the cell cycle (from 9% to 33% and from 4% to 21%, respectively) (Table 11-1 and Figure 11-2) at the expense of G_0/G_1. Such an abnormality in cell cycle progression indicates abnormal mitotic cell division in patients who have been exposed to chemicals and who have CFS. From these results, we concluded that PBLs of patients with chemical exposure and CFS grow inappropriately, not only because the signaling pathways in cells are perturbed, but also because the cell cycle clock becomes deranged and stimulatory messages become greater than the inhibitory pathways.[7,8]

However, to limit cell proliferation and avoid cancer, the human body equips cells with certain backup systems that guard against runaway division. One such backup system present in lymphocytes of CFS patients provokes the cell to undergo apoptosis. This programmed cell death occurs if some of the cell's essential components are deregulated or damaged. For example, injury to chromosomal DNA can trigger apoptosis.[1,7,8]

TABLE 11-1 **Percentage of Different Phases of Cell Cycle in Healthy Controls and Patients Exposed to Chemicals**

PHASE	HEALTHY CONTROLS	CHEMICALLY EXPOSED
G_0/G_1	88.6 ± 1.4	51.7 ± 2.4
S	8.6 ± 1.2	33.2 ± 4.3
G_2/M	3.6 ± 0.82	21.0 ± 2.6

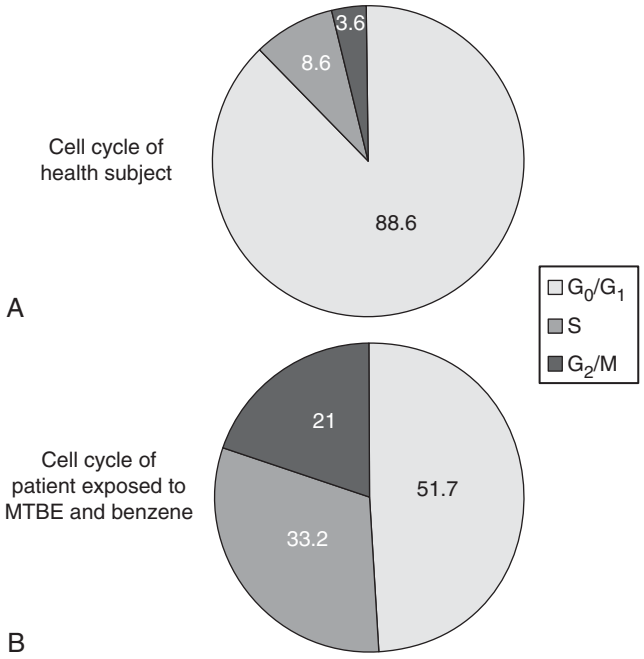

FIGURE 11-2 Cell cycle analysis of peripheral blood lymphocytes from healthy controls (A) and patients exposed to benzene (B). Note that in patients' samples, the majority of cells switched from G_0/G_1 to S and G_2/M phases.

INTRODUCTION

The erythrocyte sedimentation rate (ESR), the rate at which erythrocytes settle out of nonclotted blood in 1 hour, has been one of the most widely performed laboratory tests in the past 65 years. Used primarily to detect occult processes and monitor inflammatory conditions, the ESR test has changed little since 1918 when Fahraeus discovered that erythrocytes of pregnant women sedimented in plasma more rapidly than they did in nonpregnant women. Since its incorporation into standard laboratory diagnosis, the ESR has been shrouded with medical myths and is often misinterpreted or misused. This chapter provides a rational guideline for its use as a nonspecific measure of inflammatory, infectious, neoplastic, and cardiovascular diseases.[1-4]

ERYTHROCYTE AGGREGATION

Normally, erythrocytes settle quite slowly as the gravitational force of the erythrocyte's mass is counteracted by the buoyant force of the erythrocyte's volume. However, when erythrocytes aggregate, they sediment relatively rapidly because the proportional increase in their total mass exceeds the proportional increase in their volume.[1-4]

Therefore, the major determinant in the sedimentation rate of erythrocytes is erythrocyte aggregation, which usually occurs along a single axis (rouleaux formation). The aggregation of erythrocytes is largely determined by electrostatic forces. Under normal circumstances, erythrocytes have a negative charge and therefore repel each other. However, many plasma proteins are positively charged and neutralize the surface charge of erythrocytes, thereby reducing repulsive forces and promoting aggregation.[1-3]

The relative contribution of the various "acute phase" reactant proteins to aggregation is shown in Table 12-1. One protein that has no direct effect on the ESR in physiologic concentrations, but which is associated with certain inflammatory, degenerative, and neoplastic diseases, is C-reactive protein (CRP). Its major function is facilitation of the complement system. Like ESR, measurement of CRP is used in the monitoring of patients with chronic inflammatory conditions.[1] An elevated CRP provides evidence of an inflammatory process despite a normal ESR. Therefore, when used in conjunction with the ESR, it greatly increases the sensitivity in detecting inflammatory and/or infectious processes, especially when variables such as anemia confound the ESR.

The ESR is also elevated in patients with proteinemias (myeloma, macroglobulinemia, cryoglobulinemia, and cold agglutinin disease).[1-4] Disorders of erythrocytes such as various anemias will alter the ESR and may interfere with accurate interpretation.[1-4] Because the ESR is directly proportional to the mass of the erythrocyte and inversely proportional to its surface area, large erythrocytes sediment more rapidly than smaller cells. Therefore, in macrocytic anemia, there is an increased ESR, and in microcytic anemia, there is a decreased ESR.

Although the usefulness of ESR determination has decreased as new methods of evaluating disease have been developed, it remains quite helpful in the diagnosis of some diseases, such as temporal arteritis and polymyalgia rheumatica. Perhaps more useful is its ability to monitor these conditions as well as others, including chronic inflammatory diseases such as rheumatoid arthritis (RA), Hodgkin's disease, and other cancers. Although the use of the ESR as a screening test to identify patients

TABLE 12-1 **Relative Contribution of Acute-Phase Reactant Proteins to Erythrocyte Aggregation**

BLOOD CONSTITUENT	RELATIVE CONTRIBUTION
Fibrinogen	10
β-Globulin	5
α-Globulin	2
Albumin	1

who have serious disease is not supported by the literature, it does provide a general gauge of inflammatory processes in the body. It is well accepted that an extreme elevation of the ESR is strongly associated with serious underlying disease, most often infection, collagen vascular disease, or metastatic malignancy. Recently, there has been a growing appreciation of the value of the ESR as a marker for atherosclerosis and coronary artery disease.[5,6] In addition, as a sign of chronic low-grade inflammation, it may be helpful as a marker for other conditions as well. For example, in a study of 49,321 Swedish males aged 18 to 20 years, screened for general health and for mental and physical capacity at compulsory conscription examination before military service, there was an inverse correlation between ESR and performance on an IQ test.[7] This result indicated that low-grade inflammation, as indicated by the ESR, was associated with reduced cognitive abilities at ages 18 to 20 years.

PROCEDURES

Various methods for determination of the ESR have been developed. Currently, the Westergren method is recommended by the International Committee for Standardization in Hematology.

Westergren Method

In the standard Westergren method, the following procedure is used:

1. Dilute venous blood 4:1 with anticoagulant sodium citrate.
2. Put in a 200-mm long, 2.5-mm internal diameter, glass tube (Westergren tube).
3. Allow to stand in a vertical position for 1 hour.
4. At the end of 1 hour, the distance from the meniscus to the top of the column of erythrocytes is recorded as the ESR.

The modified Westergren method uses ethylenediaminetetraacetic acid rather than sodium citrate as an anticoagulant and is more convenient because the same tube of blood can be used for other hematologic studies. The standard and modified methods give identical results.[1-4]

Wintrobe Method

The second most commonly used method is the Wintrobe method. This method is performed with a 100-mm tube (Wintrobe tube) containing oxalate as the anticoagulant. It is more sensitive than the Westergren method in the "normal" to "mildly elevated" range; however, in the more highly elevated ESR, the short tube leads to relatively insensitive readings due to packing of cells.[2]

Results

The results of both the Westergren and Wintrobe methods are listed in Box 12-1.

BOX 12-1 **Results of Westergren and Wintrobe Methods**

Westergren (normal results)
- Men: 0-10 mm/h
- Women: 0-15 mm/h
- Children: 0-10 mm/h

Wintrobe (normal results)
- Men: <6.5 mm/h
- Women: <16 mm/h

INTERPRETATION

Several factors may result in false-positive or false-negative ESR values; the more significant of these are listed in Box 12-2. In addition, it is important to recognize that in acute disease, the change in sedimentation rate may lag behind the temperature elevation and leukocytosis for 6 to 24 hours, and in unruptured acute appendicitis the rate may be normal. In convalescence, the increased rate tends to persist longer than the fever or leukocytosis. Box 12-3 lists the most common clinical implications of changes in the ESR. An ESR value exceeding 100 mm/h has a 90% predictive value for serious underlying disease—most often infection, collagen vascular disease, or metastatic tumor.[1]

Elevated Erythrocyte Sedimentation Rate

Asymptomatic Patients

The presence of an elevated ESR as the only manifestation of a disease process is quite rare. However, when present, it can be highly significant. For example, in one study of 17 patients whose increased ESR was the sole initial clue to disease, two had tuberculosis, one had colon cancer, one had systemic lupus erythematosus, three had ankylosing spondylitis (diagnoses that typically become apparent only after several years of observation), and four men had a persistently elevated ESR several years before a myocardial infarction. The remaining patients developed myeloma, prostate cancer, psoriasis, benign monoclonal gammopathy, and pancreatic cancer.[2]

Although the ESR generally makes a small contribution to disease detection in asymptomatic persons, the presence of an elevated ESR as the only clue to illness in an asymptomatic person indicates the need for a careful diagnostic workup; it may be the first sign of an occult malignancy or a chronic inflammatory disease. Laboratory evaluation for an asymptomatic patient with an elevated ESR should include complete blood cell count with differentials, blood urea nitrogen and creatinine, alkaline phosphatase measurement, serum protein electrophoresis, urinalysis, guaiac tests of stool, and chest radiograph.[2]

An ESR that exceeds 100 mm/h is definitely associated with infection, malignancy, or connective tissue disease. Rarely does disease remain undiagnosed when the ESR is greatly elevated.[1-4] If, after further clinical evaluation, an elevated ESR cannot be explained, the ESR should be repeated in 1 month.

As a Predictor of Coronary Artery Disease

An elevated ESR in white men aged 45 to 64 years was found to be an independent risk factor for coronary heart disease in the National Health and Nutrition Examination Survey-I.[5] The risk was highest when the ESR was greater than 22 mm/h. Subsequent studies and the growing awareness that atherosclerosis

BOX 12-2 Factors Interfering with the Erythrocyte Sedimentation Rate

False Increase
- Elevated levels of fibrinogen, globulins, and cholesterol
- High room temperature
- Macrocytic anemia
- Menstruation
- Pregnancy
- Running a refrigerated blood sample before it has returned to room temperature
- Tilted erythrocyte sedimentation rate tube
- Certain drugs: dextran, methyldopa, methysergide, oral contraceptive agents, penicillamine, procainamide, theophylline, trifluperidol, vitamin A

False Decrease
- Cachexia
- Clotting of blood sample
- Elevated bile salts
- Elevated phospholipids
- >2-h delay in running the test
- High doses of adrenal steroids
- Hypofibrinogenemia
- Hyperglycemia
- Hyperalbuminemia
- Leukocytosis
- Microcytic anemia
- Newborn
- Certain drugs: adrenocorticotropic hormone, cortisone, ethambutol, quinine, salicylates

Data from references 1 and 4.

BOX 12-3 Clinical Implications of Changes in the Erythrocyte Sedimentation Rate

Increased Rate
- Acute heavy metal poisoning
- All collagen diseases
- Carcinoma
- Cell or tissue destruction
- Gouty arthritis
- Infections
- Inflammatory diseases
- Leukemia
- Multiple myeloma
- Myocardial infarction
- Nephritis
- Pneumonia
- Rheumatoid arthritis
- Syphilis
- Toxemia

Decreased Rate
- Congestive heart failure
- Polycythemia
- Sickle cell disease

is associated with chronic inflammation has given support to the use of the ESR as a prognostic indicator for the risk of coronary artery disease.[6,8] It was hypothesized and later shown that an elevated ESR reflected an elevated blood fibrinogen level (see Chapter 148 for further discussion of fibrinogen). The association of an elevated ESR as a harbinger of coronary artery disease precedes an elevated CRP, and can be viewed as an easy-to-use and inexpensive method that indirectly indicates fibrinogen level and aids in the early detection of microinflammation and eventual atherosclerotic burden, even in apparently healthy people.[9,10]

Symptomatic Patients

The ESR is sometimes used to provide confirmation of a disease process when the history and physical findings point toward a specific diagnosis. Although the ESR itself does not diagnose a specific disease, when combined with information gathered in a history and physical, as well as in conjunction with other laboratory tests, it can be a great help in the formation of a specific diagnosis.

In patients with vague, unsubstantiated illness, the ESR offers limited benefit due to the lack of specificity and the presence of a normal ESR in a wide variety of illnesses. However, the ESR offers great diagnostic benefit when other signs, symptoms, and laboratory findings are present. This is particularly true in malignancies, temporal arteritis and polymyalgia rheumatica, inflammatory arthritis, and suspected infection.

Erythrocyte Sedimentation Rate in Cancer

Malignancy is quite common in symptomatic patients with an elevated ESR. In one study, 70 (8.8%) of 790 clinic patients with an elevated ESR had cancer.[1] However, of the 70 patients with malignancy and an increased ESR, 68 had local signs that led directly to the diagnosis. Thus occult malignancy was present in only 2 of the 790 patients. In addition, the ESR is often normal in patients with cancer, indicating that the ESR should not be relied on as a test to exclude occult malignancy in patients with vague symptoms.

In a prospective follow-up of 300 patients with prostate cancer, an ESR greater than 37 mm/h was associated with a higher incidence of disease progression and death. These findings paralleled other prognostic indicators such as tumor, node, and metastasis staging, grade, performance status, and age, but also indicated that ESR provided additional value in the monitoring of these patients, and presumably others with invasive cancer.[3]

Temporal Arteritis and Polymyalgia Rheumatica

Temporal arteritis and polymyalgia rheumatica are related syndromes that can occur together or alone. Both occur in older individuals and are associated with an increased ESR. Symptoms of temporal arteritis include unilateral throbbing headache, scalp sensitivity, visual symptoms, jaw claudication, and localized thickening or loss of pulsation of the temporal artery. Polymyalgia rheumatica is a fast-developing condition characterized by pain and stiffness of the pelvis and/or shoulder girdle, in association with fever, anemia, malaise, and weight loss. It is typically self-limited to 1 to 2 years.

Determination of the ESR is of critical importance in the diagnosis and management of patients with temporal arteritis, a condition that can result in blindness due to obstruction of the ophthalmic arteries. When the clinical evidence for temporal arteritis is limited, a normal ESR reduces the probability of the disease to less than 1%. When the clinical evidence is strong, it is extremely rare to have a normal ESR. Achievement of a normal ESR by using anti-inflammatory agents, such as cortisone or the natural medicines (e.g., Curcuma longa, Fish oils, Ginkgo biloba), greatly reduces the risk of developing blindness.[1,2]

Inflammatory Arthritis

The ESR is sometimes used to distinguish inflammatory arthritis from other causes of joint symptoms. This is particularly true in the differentiation of RA, which has an elevated ESR, and osteoarthritis, which typically has a normal ESR. Because ESR is not a specific indicator of RA, it is not appropriate to place much value on it as an independent diagnostic predictor of RA. An elevated ESR in patients with joint symptoms simply indicates an active inflammatory process.[1,2]

Suspected Infection

Leukocytosis and fever are better indicators than the ESR of an acute infectious process, since the ESR is typically normal during the first stages of infection. However, the ESR is of some value in the differentiation of an intact versus ruptured appendix. Researchers demonstrated that only 2 of 25 patients with nonruptured appendicitis had an ESR of greater than 20 mm/h. In contrast, 67% of patients with ruptured appendixes had an elevated ESR.[1] CRP, however, has emerged as a more accurate measure. The value of CRP for surgical indication of appendicitis is 4.95 mg/dL.[11] CRP has also been shown to correlate better with joint sepsis than ESR.[11]

Decreased Erythrocyte Sedimentation Rate

The causes of a low ESR (0 to 1 mm/h) are listed in Boxes 12-2 and 12-3. A low ESR is generally of little significance and may actually indicate a healthy state.[1-4]

Monitoring of Disease Activity

The ESR is well recognized as an aid in monitoring the activity of such inflammatory diseases as temporal arteritis, polymyalgia rheumatica, and RA.[1-3] In general, improvements in ESR levels generally reflect clinical improvement and vice versa.

Temporal Arteritis and Polymyalgia Rheumatica

The ESR is the most widely used test for assessing disease activity in patients with temporal arteritis and polymyalgia rheumatica because these conditions have few specific clinical indicators of disease activity. However, both the ESR and clinical status need to be monitored in these patients and appropriate therapy instituted if the ESR increases or if there is a worsening in the clinical picture.[1,2,12]

Rheumatoid Arthritis

Although 5% to 10% of patients with RA have a normal ESR; the ESR generally parallels disease activity. Therefore, monitoring the patient's ESR provides invaluable feedback on therapeutic effect. An isolated elevated ESR is not useful for prognosis, but sustained extreme elevation of the ESR is associated with a poor prognosis.[1-3] It is important to note that in a meta-analysis of 63 clinical trials or observational studies of RA treatment, the authors concluded that ESR was more sensitive to change than CRP and was the preferred measure of the acute phase response in RA in clinical practice.[13]

Other Inflammatory Diseases

Other inflammatory diseases, particularly autoimmune diseases such as systemic lupus erythematosus, can be monitored by the ESR in a fashion similar to that for RA.[1-3]

SUMMARY

The ESR is a simple, valuable, and useful laboratory procedure. Although it is a nonspecific indicator of inflammation, an elevated ESR (i.e., greater than 80 mm/h) indicates the presence of significant disease in more than 95% of individuals. The ESR should never be used as the sole diagnostic test. Clinical presentation, comprehensive history, laboratory investigation, and other diagnostic procedures should always be considered when interpreting ESR results. The ESR may be used as a nonspecific gauge of therapeutic efficacy and as a monitoring tool in several inflammatory conditions, including temporal arteritis, polymyalgia rheumatica, RA, certain malignancies, and atherosclerosis.

INTRODUCTION

The Fantus test is a simple test for measuring urinary chlorides. It is used to estimate dietary sodium chloride intake. For this purpose, it has been shown to give clinically useful results if two factors are taken into consideration[1–3]:

- Concentration of urinary chloride is proportional to urinary sodium except with increased ingestion of nonsodium chloride salts (e.g., ammonium chloride or potassium chloride).
- Urinary output of sodium chloride may not be a reliable indicator of sodium intake when an individual has a salt-wasting disorder (Box 13-1).

CLINICAL APPLICATION

The Fantus test was first described by J.B. Fantus in 1936.[4] It was originally used for the diagnosis of salt and water depletion and for the differential diagnosis of edema.[5] However, this test has been found to be particularly useful for monitoring sodium intake in individuals with blood pressure disorders, including both hypotension and hypertension.

Since 1904 when Ambard and Beaujard[6] first implicated salt as a major factor in the pathogenesis of hypertension, conflicting opinions and data have confused this issue. In 1944, Kempner[7] published a classic article describing the effective treatment of essential hypertension using a salt-restricted "Rice Diet." Many studies have subsequently demonstrated the effectiveness of salt-restricted diets in treating hypertension.[8–12] Substantial evidence now exists that sodium alone does not raise blood pressure as had been previously thought, but rather that chloride also plays an important role in the elevation of blood pressure when consumed as sodium chloride, or common table salt.[13,14] Sodium bicarbonate has not been found to have the same hypertensive effect as sodium chloride.

The Fantus test is an indirect test for sodium and actually measures chloride ion concentration. Considering that sodium chloride intake, rather than sodium ion alone, is a significant factor in blood volume expansion and blood pressure elevation, the Fantus test may be more clinically useful than direct tests for urinary sodium when managing hypertension or fluid retention.[13,14]

The clinical utility of limiting salt is obvious; however, when managing hypertension with salt restriction, two difficulties arise.[15] First, effective salt restriction is difficult to maintain because of the prevalence of highly salted foods, particularly in convenience and prepared foods.

Secondly, salt must be restricted to quite low levels to be effective in the treatment of hypertension. Sodium chloride, measured in terms of sodium, must be restricted to approximately 3 g/day, compared with the 12 to 27 g of sodium per day commonly consumed in the typical Western diet.

Because the Fantus test is an inexpensive, simple in-office test, it can be effectively used to monitor salt intake where frequent sampling is useful in the management of salt-restricted diets. Salt restriction may be therapeutic in several disorders, including hypertension, congestive heart failure, premenstrual syndrome, edema, and chronic kidney disorders.

The Fantus test is also useful in monitoring salt intake in clinical conditions where restricted sodium chloride intake can be an aggravating factor, such as in Addison's disease, postural hypotension, chronic fatigue syndrome, and sodium depletion (see Box 13-1). Another use of the Fantus test is in the identification

BOX 13-1 Sodium-Wasting Conditions in Which Salt Restriction Can Be Deleterious

- Adrenocortical insufficiency
- Addison's syndrome
- Salt-wasting renal disease
- Increased sweat loss of electrolytes
- Strenuous physical exercise
- Unusual fluid losses from the gastrointestinal tract
- Chronic fatigue syndrome

of people who are ingesting excessive amounts of salt. These individuals may be without overt symptoms or signs of disease. It has been observed in animal studies that a high intake of sodium chloride decreases longevity as a factor separate from blood pressure.[16] In another study, salt-induced angiotensin elevation was found to adversely affect the myocardium in humans, even when blood pressure remained within normal limits.[17] It has been observed that the adverse effects of excess salt can persist for an extended time after excess salt ingestion has been discontinued.[18,19]

Identifying people at risk for harmful effects from excessive salt consumption is an important aspect of preventive medicine. People with risk factors for hypertension can prudently restrict salt intake. Included in this group of people at risk are individuals with chronic renal disease, those with a family history of hypertension, and individuals over the age of 50.[20]

PROCEDURE

The Fantus reagent is prepared so that the number of drops of silver nitrate ($AgNO_3$) used in the titration step can be recorded as grams of sodium per liter of urine (g Na/L urine).

Method

1. Collect a 24-hour urine sample.
2. Measure and record the 24-hour volume.
3. In a test tube add one drop of 20% potassium chromate (K_2CrO_4) solution to 10 drops of the sample of the 24-hour urine specimen.
4. Titrate (add one drop at a time) with the 2.9% silver nitrate ($AgNO_3$) solution.
5. Record the number of drops needed to turn the color from yellow to brown as g sodium/L.

(If sodium chloride is present in too low of a concentration to accurately measure, you can use 20 drops of urine. Each drop of $AgNO_3$ is then equal to 0.5 g Na/L.)

Reagents

- $AgNO_3$: 2.9% aqueous solution
- K_2CrO_4: 20% aqueous solution

Results

- Typical Western diet: 12 to 27 g Na/24 h
- Salt-restricted diet: 0.6 to 3.5 g Na/24 h

INTERPRETATION

Normally, urinary sodium varies with the sodium chloride intake, reflecting the salt content of the diet. The typical Western diet contains 12 to 27 g of sodium in a 24-hour period (80 to 180 mEq/24 hr).[21] On a salt-restricted diet, the goal is usually to reduce 24-hour urine sodium to approximately 3 g Na/24 h.[20] The minimum 24-hour sodium intake considered safe is 0.6 g Na/24 h for healthy individuals with intact adrenocortical function (see Box 13-1).

A salt intake of 3 g Na/day with an intake of 2750 mL of water from both solids and fluids corresponds to the average water turnover for a 70-kg adult. After evaporation from the lungs and other losses, the amount of water excreted by the kidneys is approximately 1500 mL/24 h.[5] This produces a urinary sodium excretion of 3 g in 24 hours and a urinary sodium concentration of 2 g/L. A 24-hour urine sample can be used to more accurately estimate 24-hour sodium intake (i.e., 24-hour urine volume x urinary sodium concentration = 24-hour sodium intake).

INTRODUCTION

The analysis of fatty acids in blood provides useful information about fatty acid deficiencies and imbalances and can also reveal a functional need for certain vitamins and minerals. Clinical interventions involve changes in food selection or supplementation with selected nut or seed extract oils and required micronutrients. Laboratory reports of fatty acid profiles typically list the fatty acids by structural type in the following order: ω-3–polyunsaturates, ω-6–polyunsaturates, monounsaturates, even-numbered saturates, odd-numbered saturates, and, finally, trans-monounsaturates. Several ratios may be calculated, and for plasma, the total fatty acid concentration may be calculated by summing the individual components and expressing the total in milligrams per deciliter, consistent with the units for serum triglycerides that are directly related to total fatty acid content.

METHODOLOGIC ISSUES

Plasma Versus Erythrocyte Fatty Acid Profiles

A plasma fatty acid profile is an amplification of the standard serum triglyceride analysis. In both cases, the fatty acids are present in lipoprotein particles. Instead of measuring only the total of all fatty acids present, the profile test reports the individual concentrations of each fatty acid. An individual with high serum triglycerides has higher levels of many individual fatty acids in plasma. Of course, any condition associated with elevated serum triglycerides is likewise revealed as elevated plasma fatty acids. Patterns of high or low concentrations in plasma depend on recent dietary intake, composition of adipose fat, and rates of metabolic conversion. Plasma is the preferred specimen for routine evaluation of essential fatty acid (EFA) status because interpretation is less complicated by metabolic issues that bear upon fatty acid levels found in erythrocytes.

In contrast, erythrocyte membrane fatty acid profiling is commonly used to investigate metabolic conversion problems and genetic diseases. The erythrocyte membrane is 45% fatty acids in the form of various phosphatides and glycolipids. The procedure used for profiling measures total concentrations of individual fatty acids per milliliter of packed cells. Erythrocyte levels reflect those present in most tissues. Both erythrocyte and plasma have been used to monitor brain fatty acid balance in Zellweger syndrome.[1] Both specimens have also revealed the need to supplement infant formulas with ω-3 fatty acids.[2]

The triglyceride-lowering drug gemfibrozil causes a profound suppression of erythrocyte unsaturated fatty acids, even in the presence of high concentrations of the same compounds in plasma. The effect is apparently due to stimulation of the peroxisomal β-oxidation system.[3] Because of the metabolic effect of the drug, a patient consuming a diet high in olive oil (largely oleic acid) may show low levels of oleic acid in erythrocyte membranes while maintaining high oleic acid in plasma. Thus, plasma profiles show the dietary changes, and erythrocyte fatty acids show the metabolic impact of the drug.

Concentration Versus Percentage

Before 1996, virtually all clinical laboratories reporting fatty acid levels expressed results as a percentage of total concentration. Individual concentrations could not

be reported due to the lack of pure standards necessary to build calibration curves. The reporting of "relative area" data has some utility but leaves important points obscured. The most abundant fatty acids are present at concentrations 50 times higher than those of the lesser components.[4] Percent area calculations cause the most abundant components to have a disproportionate impact on the minor components. If α-linolenic acid (ALA) is the same in two cases, for example, whereas palmitic acid is low in the first and high in the second, the percent ALA can appear high in the first and normal in the second because palmitic acid makes up so much of the total, and the ratios are calculated by dividing by the total.

With the availability of pure standards, it is now possible to measure the concentrations of each fatty acid. Because the molecular weights span a range of more than seventy-fold for these homologous compounds, molar units allow more meaningful comparisons. This unit also simplifies interpretation of plasma fatty acids, where the total of all fatty acids is directly proportional (and closely equivalent) to the values for total triglycerides from a standard serum chemistry assay. For erythrocytes, concentration is based on packed cell volume or on total lipid extract volume.

INTERPRETATION OF ABNORMAL FATTY ACID RESULTS

Table 14-1 summarizes common fatty acid abnormalities and interventions for correction using specific dietary oils. Table 90-4 in Chapter 90 lists the typical symptoms and diseases associated with various fatty acid abnormalities.

Omega-3 (n-3) Fatty Acids

Alpha Linolenic Acid (18:3ω-3)

Many edible plants produce this 18-carbon polyunsaturated fatty acid, but because of the small amounts of fresh vegetables consumed by many people, it is one of the least abundant of the EFAs in most diets. It is found in relatively high amounts in flax, hemp, canola seed, soybean, walnut oils, and in dark green leaves. It must be supplied by such foods because human tissues lack the necessary enzymes for its formation. Dietary insufficiencies of ALA and its ω-6 counterpart, γ-linolenic acid (GLA), play central roles in several diseases (see Tables 90-4 and 90-5 in Chapter 90). The wide range of symptoms and disease associations is due to their functions in processes of membrane integrity and cell activity regulation by eicosanoids (20-carbon fatty acids). Correction of low body pools of ALA requires dietary changes or the use of dietary supplements containing ALA. Table 14-2 lists food sources of ALA. The dietary origin of ALA deficiency disorders can be seen by inspecting the ALA content of corn, safflower, and peanut oils that are so predominant in modern diets.

Eicosapentaenoic Acid (20:5ω3)

Insufficiencies of eicosapentaenoic acid (EPA) are likely the most prevalent fatty acid abnormality affecting the health of individuals in Western societies. Low levels in plasma, erythrocytes or blood spot specimens are indicative of insufficiency. Arthritis, heart disease, and accelerated aging result from direct or indirect effects of inflammatory responses that may be modulated by

TABLE 14-1 **Summary of Common Abnormalities Found in Profiles of Fatty Acids in Plasma and Erythrocytes**

NAME	ABNORMALITY	METABOLIC ASSOCIATION	POTENTIAL RESPONSES*
		Omega-3 polyunsaturated	
Alpha linolenic	L	Essential fatty acid	Add flax or fish oils, or both
Eicosapentaenoic	L	Eicosanoid substrate	Add fish oils
Docosapentaenoic	L	Nerve membrane function	Add fish oils
Docosahexaenoic	L	Neurologic development	Add fish oils
		Omega-6 polyunsaturated	
Linoleic	L	Essential fatty acid	Add corn or borage oil
Gamma linolenic	L	Eicosanoid precursor	Add evening primrose oil
Eicosadienoic	H	Desaturase inhibition	Zinc
DGLA	L	Eicosanoid substrate	Add borage oil
Arachidonic	H	Eicosanoid substrate	Reduce red meats
Docosadienoic	H	Increase in adipose tissue	EFA and glycemic control
Docosatetraenoic	H	Increase in adipose tissue	EFA and glycemic control
Mead	H	EFA deficiency	Add balanced EFA
		Monounsaturated	
Vaccenic	H	Biotin deficiency	Biotin
Myristoleic	H	Membrane fluidity	Correct low EFA levels
Palmitoleic	H	Membrane fluidity	Correct low EFA levels
Oleic	H	Membrane fluidity	Correct low EFA levels
11-Eicosenoic	H	Membrane fluidity	Correct low EFA levels
Nervonic	L	Neurologic development	Add fish or canola oils
Erucic	L	Nerve membrane function	Add peanut oil
		Saturated	
Capric acid	H	Multiple acyl dehydrogenase deficiency	Add riboflavin
Lauric	H	Multiple acyl dehydrogenase deficiency	Add riboflavin
Myristic	H	Multiple acyl dehydrogenase deficiency	Add riboflavin

TABLE 14-1 Summary of Common Abnormalities Found in Profiles of Fatty Acids in Plasma and Erythrocytes—cont'd

NAME	ABNORMALITY	METABOLIC ASSOCIATION	POTENTIAL RESPONSES*
Palmitic	H	Cholesterogenic	Reduce saturated fats; add niacin
Stearic	H	Elevated triglycerides	Reduce saturated fats; add niacin
Arachidic	H	Elevation of these fatty acids occur in hypertriglyceridemia or perxisomal deficiency	
Behenic	H		
Lignoceric	H		
Hexacosanoic	H		
Odd-numbered			
Pentadecanoic	H	Elevation of these fatty acids can be due to deficiency of biotin or vitamin B12 or elevated intestinal propionate-producing bacteria	Assess need for additional biotin or vitamin B12
Heptadecanoic	H		
Nonadecanoic	H		
Heneicosanoic	H		
Tricosanoic	H		
Trans-fatty acids			
Palmitelaidic	H	Metabolic interference	Eliminate hydrogenated oils
Elaidic or total C18 trans	H		
Ratios and indexes			
LA/DGLA	H	Δ6 desaturase enzyme	Add zinc
DGLA/EPA	L	Eicosanoid imbalance	Add borage oil
AA/EPA	H	EFA deficiency	Add fish oils
Triene/Tetraene	H	Overall fatty acid status	Add fish oils
P/S ratio	H	Overall fatty acid status	Add balanced EFA
Stearic/oleic (RBC)	L	Rises as therapeutic efficacy marker for some cancers	

*Adult supplement doses usually range from 1 to 3 g/day in the form of extracted nut and seed oils that may contain 30%-60% of the fatty acid by weight. See appropriate chapters for supplementation levels for vitamins and minerals indicated.

AA, arachidonic acid; DGLA, dihomogammalinolenic acid; EPA, eicosapentaenoic acid; EFA, essential fatty acid; H, high; L, low; LA, linoleic acid; MAD, multiple acyl-coenzyme-A disorder; P/S, polyunsaturated/saturated (fatty acid ratio); RBC, red blood cell.

Sunflower oil	0	65.7	0

raising EPA levels. Supplementation with EPA-rich fish oils (Table 14-3) aids in the prevention of cardiac arrhythmias.[5] Significant reduction in total cholesterol and triglyceride has been achieved with a combination of garlic concentrate (900 mg/day) and fish oil supplementation.[6] EPA is the precursor of the 3-series prostanoids and leukotrienes that moderate the proinflammatory effects of the 2-series derived from arachidonic acid (AA). Although EPA can be produced from the essential fatty acid ALA, dietary intake of this fatty acid is generally poor. The conversion also requires the action of the δ-6 desaturase enzyme, which may be low due to inadequate zinc, magnesium, or vitamins B_3, B_6, and C.[7] Such enzyme impairment would be indicated if EPA is low and ALA is normal or high. High levels of saturated, monounsaturated, and trans-fatty acids and cholesterol also slow the conversion of ALA to EPA (as well as GLA to dihomogammalinolenic acid [DGLA]). Dietary supplementation of EPA is an important part of nutritional support in patients with compromised immune responses, including postoperative and trauma.[8] Fish oil supplementation lowers triglycerides without effect on glycemic control in type 2 diabetes.[9]

Docosapentaenoic Acid (22:5ω3), Docosahexaenoic Acid (22:6ω3)

Growth and development of the central nervous system depend on the presence of an adequate amount of the long-chain, highly

unsaturated fatty acids docosapentaenoic acid (DPA) and docosahexaenoic acid (DHA).[10,11] Attention deficit hyperactivity disorder and failures in development of the visual system in EFA deficiencies are two examples of this dependency.[12] DHA is an important member of the very long-chain fatty acids (C22-C26), which characteristically occur in glycosphingolipids, particularly those in the brain. The levels in breast milk are correlated with the mother's intake of fish oils, which are rich sources of DHA and DPA.[13] Plasma DHA levels should be checked as early as possible in pregnancy. The finding of low DHA in plasma or erythrocytes also justifies the use of supplemental DHA for depression.[14]

Omega-6 (n-6) Fatty Acids

Linoleic Acid (18:2ω6)

Linoleic acid (LA) is the most abundant polyunsaturated fatty acid (PUFA) in most human tissues. Low levels in plasma or erythrocytes indicate dietary insufficiency, which leads to various symptoms (see Table 90-4 in Chapter 90). Some of these symptoms result from a lack of LA in membranes, where it has a role in structural integrity. Most, however, are from failure to produce the 1-series and 3-series prostanoids. Neonatal LA status of this fatty acid can be insufficient.[15] Fetal LA and DHA are correlated with maternal red blood levels.[16] However, because dietary sources (especially corn oil) are abundant, LA may be above normal range in some adults. Excessive LA can contribute to an overproduction of the proinflammatory 2-series local hormones derived from AA.

Although the n-6 fatty acids, especially LA, are widely imputed as health risk factors because of their relative overabundance in modern diets, it is important to recognize that the clinical imperative is to discriminate excess from deficiency status. The only sure way to know whether a patient is in n-6 fatty acid deficit or excess is to perform a laboratory evaluation of fatty acid status.

Gamma-Linolenic Acid (18:3ω6)

GLA is the precursor of DGLA, the parent of the 1-series prostanoids. GLA is found in hemp, borage, blackcurrant, and evening primrose oils. It can be produced in human tissues by the action of desaturase enzymes on LA. Use of 1.4 g/day in the form of borage seed oil resulted in a clinically important reduction in the signs and symptoms of rheumatoid arthritis.[17] In cases of cancer, it is especially important that low levels of GLA should not be supplemented without added ω-3 fatty acids because ω-6 fatty acids can enhance tumor formation and growth, whereas ω-3 fatty acids tend to inhibit tumors.[18] GLA corrects most of the biological effects of zinc deficiency.[19]

Dihomogammalinolenic Acid (18:3ω6)

Diets low in LA are usually also low in DGLA. An insufficiency of this fatty acid impairs a wide range of cellular functions and tissue responses. DGLA is the precursor for the 1-series prostanoids that moderate the proinflammatory 2-series effects. When testing reveals low levels of DGLA, supplementation with borage or evening primrose oils should be considered.

Arachidonic Acid (18:4ω6)

Because of the prevalence of corn and corn oil products in feed for cattle and hogs, diets high in these red meats are usually rich in AA. AA is a 20-carbon or eicosanoate fatty acid that serves as a substrate for the cyclooxygenase and lipoxygenase enzymes, leading to the production of the 2-series prostanoids and leukotrienes. Several of these products have potent proinflammatory and thrombogenic activity. High AA also promotes gallstone formation by stimulating mucin production in the gallbladder mucosa.[20] Elevated AA is a frequent finding in profiles of fatty acids in plasma or erythrocytes. Such findings should trigger counseling regarding dietary AA reduction and appropriate supplementation to restore n-3/n-6 balance. However, deficiency of AA produces signs of EFA deficiency, so adding ω-6 oils is needed when low levels are found. AA levels decline rapidly when EPA levels are elevated by excessive use of flax or fish oils.

Mead Acid (20:3ω9)

Individuals with good fatty acid status have low levels of the ω-9 PUFA called Mead acid. Mead acid is produced in human tissues by repeated desaturation of stearic acid when there is chronic deficiency of n-3 and n-6 fatty acids.[15] Although Mead acid cannot participate in eicosanoid formation, it does serve to mimic the membrane fluidity contributions of PUFAs derived from essential precursors. Because the enzymes for Mead acid formation are contained in peroxisomes, conditions that cause peroxisome proliferation can produce elevated levels of Mead. Because one such condition has high levels of n-3 and n-6 fatty acids, Mead acid elevation is not indicative of EFA deficiency when such patterns are found. Mead acid is the triene mentioned in the discussion of the triene/tetraene ratio near the end of this chapter.

Monounsaturated Fatty Acids

Vaccenic Acid (14:1ω9), Palmitoleic Acid (16:1ω9), and Myristoleic Acid (18:1ω7)

The ratio of vaccenic acid to palmitoleic acid is a marker of biotin deficiency.[21] Vaccenic acid has effects on membrane fluidity, possibly due to the fact that the ω-7 double bond does not align with the much more abundant ω-9 positions of the majority of fatty acids present in the membrane. Myristoleic and palmitoleic acids are normally found in small amounts because the desaturated

enzymes have weak affinity for their saturated fatty acid precursors, myristic and palmitic acids. In long-term EFA deficiency, the low concentrations of PUFAs allow higher rates of formation of myristoleic and palmitoleic acids.

Oleic Acid (18:1ω9)

Oleic acid is present in virtually all whole foods and is easily produced by the fatty acid synthetic pathways present in normal human hepatic cells. It constitutes 15% of the fatty acids in erythrocyte membranes. Because of the presence of the double bond in the center of the molecule, it helps to govern the fluidity of the membrane matrix.

The pathogenesis of atherosclerosis involves accumulation of foam cells along the arterial wall. Lipids that transform macrophages into these foam cells are provided by oxidized low-density lipoproteins (LDLs). Oleic acid is the principal lipid of a class that makes LDLs resistant to oxidation, and thus a diet rich in this fatty acid reduces foam cell accumulation rates and thereby lowers the chances of atherosclerosis[22] (see Chapter 148 for a more complete discussion).

In tumors, the expression of genes for metabolizing fatty acids is altered so that stearic acid levels increase relative to oleic acid, causing a profound reduction in the ratio of stearic to oleic acids.[23] One likely outcome of this shift is an increased fluidity of the tumor cell membrane, resulting in more rapid movement of nutrients and waste products and allowing for a faster metabolic rate. The stearic/oleic ratio is used to monitor the effectiveness of cancer therapy.[24]

High oleic acid intake (usually as olive oil) can raise total oleic acid content of plasma above the reference range. This finding alone is not highly significant because oleic acid is a cholesterol neutral fatty acid and is produced in humans from stearic, so it is not an EFA.

Erucic Acid (22:1ω9)

This fatty acid is apparently one of the components responsible for the favorable response of individuals with adrenal leukodystrophy (ALD) to preparations containing canola and mustard seed oils.[25] Other studies using Lorenzo oil containing glycerol trierucate revealed no appreciable changes in brain lipid content.[26] In Zellweger syndrome, where peroxisomes are absent, erucic and adrenic acids accumulate. It is speculated that either the anabolic enzymes are inhibited from producing sphingolipids or the catabolic enzymes are stimulated to faster clearance of the offending products.[27]

Nervonic Acid (24:1n9)

Nervonic acid contains the longest chain of carbon atoms of all monoenoic fatty acids present at appreciable levels in plasma and erythrocytes. The unique structure of nervonic acid confers special properties to nerve membranes, where it is found in highest concentrations. The myelin sheath is especially rich in nervonic acid. Nervonic acid accumulation in red blood cells yields information on cerebrum maturation in premature infants.[28] Demyelination in ALD is associated with an accumulation of long-chain saturated fatty acids, such as 26:0, stemming from a genetic defect in the peroxisomal β-oxidation system responsible for the chain shortening of these fatty acids. Long chain monoenoic acids, such as erucic acid, 22:1(n9), can normalize elevated serum levels of 26:0 in ALD by depressing their biosynthesis from shorter chain saturated fatty acids.[29] Impairment in the provision of nervonic acid in demyelinating diseases is indicated, suggesting that dietary therapy with oils rich in very long chain, monoenoic fatty acids may be beneficial in such conditions.

Saturated Fatty Acids

Capric Acid (10:0), Lauric Acid (12:0), Myristic Acid (14:0)

These medium-chain saturated fatty acids correspond to the dicarboxylic acids that accumulate in the fatty acid catabolic disorders known as multiple acyl-coenzyme-A (CoA) dehydrogenation disorders (MADs).[30] One type of this enzyme defect is responsive to riboflavin at levels far above normal intakes.[31] A pattern of low levels of the shorter chain fatty acids and high levels of longer chain fatty acids may indicate a fatty acid restricted diet, in which case there is a stimulation of hepatic synthesis and elongation enzymes.

Palmitic Acid (16:0) and Stearic Acid (18:0)

The liver can convert fatty acids into cholesterol. Although any fatty acid can enter this pathway, palmitic acid is the most stimulatory one known and high levels lead to increased serum cholesterol levels and thus to increased risk of atherosclerosis, cardiovascular disease, and stroke. Most other fatty acids are either cholesterol neutral or have reverse effects, as in the case of EPA. Palm kernel and coconut oils are rich sources of palmitic acid. Palmitic acid is also the principal fatty acid product of human fatty acid synthesis, which is stimulated by hyperinsulinemia and by diets high in simple carbohydrates.

Stearic acid is a saturated fatty acid that is two carbon atoms longer than palmitic acid and is similarly cholesterogenic. High levels in plasma are therefore a risk factor in atherosclerotic vascular disease. Abnormal levels in erythrocyte membranes cause alteration in membrane fluidity. Low levels give increased fluidity, which is associated with active tumor proliferation.

Behenic Acid (22:0), Lignoceric Acid (24:0), Hexacosanoic Acid (26:0)

Accumulation of certain long-chain fatty acids is associated with degenerative diseases of the central nervous system, such as ALD. A large number of known genetic disorders involve accumulation of sphingolipids, usually due to the lack of enzymes necessary to maintain the turnover of membrane components. Behenic, lignoceric, and hexacosanoic acids, as well as the unsaturated members of the C22-24 classes, especially nervonic acid, are found elevated in such cases.

Odd-Numbered Fatty Acids

Pentadecanoic Acid (15:0), Heptadecanoic Acid (17:0), Nonadecanoic Acid (19:0), Heneicosanoic Acid (21:0), and Tricosanoic Acid (23:0)

Fatty acids with odd numbers of carbon atoms are produced primarily by initiating the synthetic pathway with the three carbon compound propionic acid. Vitamin B_{12} is required for the conversion of propionate into succinate for oxidation in the central energy pathways.[32] Deficiency of vitamin B_{12} results in accumulation of propionate and subsequent buildup of the odd-numbered fatty acids. The initiation of fatty acid synthesis is a biotin-dependent step. In biotin deficiency, the rate in which acetyl-CoA is converted into malonyl-CoA is reduced, allowing propionate to enter in greater amounts. Elevated levels of odd-numbered fatty acids have been shown to occur in human plasma phospholipids and in the plasma, heart, and liver of experimental animals with biotin deficiency.[33,34]

Bacteria in the gut of ruminants produce large amounts of propionate, which is absorbed and enters the metabolism. Consequently, the intake of animal and dairy products favors higher

levels of odd-numbered fatty acids. Alternatively, it is possible that the bacteria in the human gut could produce sufficient amounts of propionate to lead to an elevation in the odd-carbon fatty acids.[35] This would only occur under conditions of significant gut dysbiosis.

The association between vitamin B_{12} and abnormal fatty acid synthesis provides a rationale for the neuropathy of cobalamin deficiency. Odd-chain fatty acids build up in membrane lipids of nervous tissue, resulting in altered myelin integrity and demyelination, leading to impaired nervous system functioning.[36]

Trans-Fatty Acids

Palmitelaidic Acid (16:1ω9t), Elaidic Acid (18:1ω9t), and Other Trans-Fatty Acids

The trans-fatty acids, elaidic and palmitelaidic acids, are prevalent in most diets because of the widespread use of hydrogenated oils in food products. Because these fatty acids contain a *trans* double bond they behave like saturated fats, leading to higher cholesterol levels.[37] In contrast, they mimic unsaturated fats in binding to desaturated enzymes and interfering with the normal desaturation rates. The net effect raises plasma LDL and lowers high-density lipoprotein.

The consensus among experts in lipid nutrition is now so strong that ingestion of foods containing hydrogenated oils is a health risk that products containing them have been banned in some areas. The bacteria in the gut of ruminant animals produce small amounts of these fatty acids, which is the reason that beef and milk contain 1% to 3% of elaidic acid. If plasma or erythrocyte levels of trans-fatty acids are elevated, foods containing hydrogenated oils need to be avoided. Foods that generally contribute the greatest amounts of trans-fatty acids include stick margarine, peanut butters, and bakery products such as breads, rolls, cookies, crackers, pies, and cakes.

Two other 18-carbon isomers, petroselinic and trans-vaccenic acids, are usually present in smaller amounts than elaidic acid. Because the clinical concern is only the total accumulation of trans-fatty acids, some laboratories report the total C18 trans-fatty acid concentration rather than attempting to isolate each isomer.

Fatty Acid Ratios

These calculated values provide a quick guide to the balance between two parameters. Sometimes valuable insights into imbalances are found in ratio values, although the individual components are within normal limits.

Linoleic Acid/Dihomogammalinolenic Acid Ratio

The ratio of LA to DGLA increases when zinc deficiency or excesses of saturated, monoenoic, or trans-fatty acids inhibit the δ-6 desaturase enzyme. Under these conditions, the enzyme cannot convert the substrate (LA) to the product (DGLA) fast enough. The production of all desaturation products is affected, including EPA and AA. These longer chain polyunsaturated fatty acids then must be supplied from the diet or supplemented forms.

Dihomogammalinolenic Acid/Eicosapentaenoic Acid Ratio

The balance of 20-carbon or eicosanoic fatty acids is critical for proper supply of the prostanoid and leukotriene 1-, 2-, and 3-series local hormones that control a host of cellular functions and responses. The DGLA/EPA ratio is typically high due to DGLA being elevated relative to EPA, indicating a need for EPA sources such as fish oils. When the ratio is low, sources of DGLA (borage or evening primrose oil) are indicated.

Arachidonic Acid/Eicosapentaenoic Acid Ratio

This ratio allows a quick comparison of the relative amounts of these two eicosanoid precursors. An abundance of AA is quite common in Western diets high in meat and corn oil and can result in the elevation of the AA/EPA ratio. This is one of the indicators that extra ω-3 fatty acids, including EPA of fish oils, would be beneficial.

Triene/Tetraene Ratio (Mead/Arachidonic Acid)

The ratio of the triene Mead acid to the tetraene AA has been used as a further marker of EFA deficiency. This ratio is commonly used in studies of EFA deficiency.[38] In cases where long-term EFA supplementation has stimulated the production of Mead acid with concurrent elevation of AA, the ratio of the two is not above the normal reference limit. Only when the Mead elevation is found without high levels of PUFAs is a high triene/tetraene ratio indicative of EFA deficiency.

Red Cell Stearic/Oleic Index

The ratio of stearic to oleic acids in red cell membranes has been found to be a strong indicator of the presence of malignant tissue, since it reflects the lowered ratio found in malignant tissue cell membranes.[39] Values below 1.1 have been associated with the presence of malignancy. The ratio was found to respond to hormonal therapy for prostatic cancer and, in studies after surgical cures, individuals who maintained this ratio above 1.1 had no tumor recurrences.

The Omega-3 Index

The ω-3 index is defined as the sum of EPA and DHA expressed as a percentage of the total fatty acid content of red blood cell membranes. Because the ω-3 index half-life is 4 to 6 times longer than serum or plasma EPA and DHA, it better reflects long-term exposure to these fatty acids. It also has the advantage of not being influenced by the fasting or fed state.[40]

An analysis of related laboratory and clinical data found that the ω-3 index was inversely associated with risk for mortality because of cardiovascular disease. An ω-3 index of more than 8% was associated with the greatest protection, whereas an index of less than 4% was associated with the least protection.[41] While less precise, whole blood ω-3 content was also significantly associated with risk for sudden death. In a prospective trial using data from the Physicians' Health Study, men whose blood levels of ω-3 fatty acids were in the third and fourth quartiles had relative risks of sudden death of 0.28 and 0.19, respectively, compared to those in the lowest quartile.[42] The ω-3 index was associated with improved cardiovascular risk factors independent of body fatness in younger overweight and obese individuals, suggesting that achieving an optimal ω-3 index may negate some of the risk associated with excess weight.[43]

SUMMARY

Recent advances in laboratory methodologies now allow measurement of absolute, as well as relative, levels of essential, nonessential, and potentially damaging types of fatty acids in the blood. The research literature now provides guidance for interpretation of the clinical significance of various fatty acid patterns. Fatty acid manipulation through diet and supplementation is a powerful therapeutic resource (see Chapter 90).

INTRODUCTION

The percentage of people with food allergies or sensitivities is unknown because many people do not attribute their symptoms to the food they eat. In 2004, it was estimated that 6% of children and 4% of adults in America had immunoglobulin-E (IgE) mediated food allergies[1] and that 20% of the population altered their diet due to adverse reactions to foods.[2,3] It is clear that food reactions are common and the prevalence of food allergies specifically is rising.[1] There are a variety of reactions a person can have to food including:

1. Psychological reactions to food (via exorphins or food aversions)
2. Toxic reactions to food (food poisoning or contaminated food)
3. Immune-mediated reactions to a food (type I, II, III, or IV hypersensitivity)
4. Food intolerance reaction (enzyme deficiency or hypersensitivity to a food component or additive)

This chapter focuses on the immune-mediated reactions to food, also referred to as food allergies.

The specific nomenclature used for food allergies has been defined in position statements written by the European Academy of Allergy and Clinical Immunology (EAACI) nomenclature review committee. Allergy reactions are defined as a "hypersensitivity reaction initiated by immunologic mechanisms."[4] This includes food reactions mediated by any antibody (IgE, IgG, IgA, or IgM), as well as cell-mediated reactions (as seen in contact dermatitis).[5] Although this is the strict definition of food allergy, the same article also stated that, "Food-specific IgG antibodies in serum are not of clinical importance but merely indicate previous exposure to the food. If IgE is involved in the reaction, the term IgE-mediated food allergy is appropriate. All other reactions should be referred to as nonallergic food hypersensitivity."[5] Hypersensitivity is defined as a way to "describe objectively reproducible symptoms or signs initiated by exposure to a defined stimulus at a dose tolerated by normal persons."[5] These definitions stated that food reactions mediated through IgG or IgA antibodies would strictly be defined as a "food sensitivity." The clinical significance of IgG and IgA antibodies is still being debated in the scientific and medical communities.[6] Most natural medicine practitioners call IgG- and IgA-mediated reactions "food allergies" because the reaction is associated with an antibody response. Food allergies will be defined here as any response to food that is immune mediated, including antibody responses (IgE, IgG, IgA, and IgM), as well as cell-mediated food reactions.

The discussion of definitions also extends into food allergy symptoms. The scientific community typically defines food allergy symptoms as IgE antibody mediated (type I or II hypersensitivity reactions). IgE associated disorders include immediate-type gastrointestinal hypersensitivity, oral allergy syndrome, acute urticaria and angioedema, allergic rhinitis, acute bronchospasm, and anaphylaxis. Symptoms include reddening of the skin; hives; pruritus of skin, mouth, or throat; swollen lips or eyelids; tightness of the throat; wheezing; difficulty breathing; coughing; vomiting; or diarrhea.[7,8] Most of these symptoms happen right after eating the offending food. Mixed IgE- and cell-mediated food reactions cited in the literature include atopic dermatitis,[9-12] asthma,[13,14] eosinophilic esophagitis,[15-17] and eosinophilic gastroenteritis.[18] Food reactions mediated by cellular (non-IgE mechanisms) include contact dermatitis,[19] food-induced pulmonary hemosiderosis,[20,21] celiac disease,[22] and food protein-induced enterocolitis syndrome.[23,24] Many natural medicine practitioners recognize a wider array of food-related disorders and symptoms that can

affect almost any system in the body. Symptoms may include diarrhea, constipation, abdominal bloating, gas, urinary irritation, rashes (including eczema and psoriasis), tinnitus, nasal congestion, chronic sinus or ear infections, joint pain, headaches, foggy thinking, fatigue, and mood disturbances.[25-28] Many of these symptoms are delayed, sometimes taking a few days to appear. Because of the variety of symptoms and the time it takes people to show a reaction to some foods, food allergy testing can be useful.

Various types of food allergy testing methods are used as tools to identify a person's reactive foods. Different tests are appropriate depending on the immunologic reaction a person is trying to discover. Food allergy or sensitivity testing can be a great motivational tool to encourage dietary changes, showing people in full color their specific reactive foods. People are often more willing to change their diet after a test provides "proof" that a particular food is reactive. Food allergy tests can also be useful when patients are unable or unwilling to do a full elimination diet, or when they are not aware of the food-related physical symptoms present in their body. Although an elimination diet is still the gold standard for food sensitivity testing, the time and diligence it takes to do a proper elimination diet is often overwhelming. An accurate and reproducible food allergy test allows nutritious foods to remain in a patient's diet while eliminating reactive foods. This chapter provides a review of the immunology of food allergies and then specifically examines the different food allergy testing methods.

IMMUNOLOGY OF FOOD ALLERGIES

Healthy individuals do not have food allergies or sensitivities. Instead they eat foods, digest them well, absorb what they need, and their immune system develops "oral tolerance" to the food. Oral tolerance describes how the body learns not to react to an antigen (food) when it is delivered through the oral route.[29-31] The factors that influence tolerance include the person's genetics, digestive function, and the nature and form of the food when it is consumed. Proteins induce tolerance more than lipids and carbohydrates,[32] and proteins given in a soluble form induce tolerance more than those that are aggregated.[29] Low doses of antigen activate regulatory/suppressor T cells, generally described as T_H3 cells (which can be both CD4 and CD8T cells).[33,34] The mucosal immune system consists of regulatory and suppressor T cells (T_H3 cells) in Peyer's patches and mesenteric lymph nodes that produce transforming growth factor-β (TGF-β). The role of TGF-β in the body is to promote B-cell class switching to IgA and to act as a general immunosuppressant for both T- and B-cell responses.[35,36] In this way, we can accept food into the body while still fighting pathogens (bacteria, viruses, parasites, or toxins).

Increased intestinal permeability is related to increased aggressive inflammation and lack of tolerance. It appears that increased permeability throughout the intestine allows food antigens to pass through the disrupted tight junctions and, in animal models, induces anaphylaxis[37-39] (see Chapter 20, Intestinal Permeability Assessment). When antigens are absorbed through the paracellular spaces, the mucosa-associated lymphoid tissue does not get the proper stimulation to induce a tolerance response. Data are conflicting regarding the integrity of the mucosal barrier in children with various gastrointestinal diseases.[40-42] The role of intestinal permeability is critical for our understanding of food allergies and may play a role in a variety of types of immune-mediated food reactions. Natural medicine practitioners often talk about healing the intestines, leaky gut, and decreasing inflammation. These types of treatments are most likely aimed at increasing the tolerance response in the intestines.

Food allergies may develop when the regulatory system falters due to defects in TGF-β or when the intestinal epithelial barrier is breached. Both of these may contribute to a reactive individual developing an antibody-mediated food reaction. When a food is taken up by Peyer's patches in a reactive individual, CD4T cells specific for the food make T_H2 cytokines, including IL-4 and IL-13. These cytokines cause B cells specific for the protein in the food to make IgE and induce mast cell activation and growth (IL-4 and IL-9).[43,44] IgG is also produced in response to food antigens, although the mechanisms leading to the production of total IgG and its subclasses are not fully elucidated at this time. Allergic sensitization to allergens was originally attributed to a dysregulation of the Th1/Th2 balance. New subsets of T cells have been shown to induce allergies or have an effect on the immune regulatory balance. These cells include Th17 cells[43] and nonclassical T cells such as natural killer T cells,[45] γδ T cells, and subsets of CD8T cells (Tc1 and Tc2 cells).[43,44]

For type I hypersensitivity reactions, antigen-specific IgE is produced by B cells. Elevated levels of antigen-specific IgE allergies are found in allergic people even with antigen avoidance for several years.[46,47] Once IgE antibodies are made to a particular food, they attach to Fc receptors on mast cells and eosinophils. When the antibody binds to its triggering food, the cells degranulate, causing traditional allergy symptoms, including hives, diarrhea, and gastric distress.[48]

Types of Hypersensitivity Reactions

Type I

Type I hypersensitivity reactions involving IgE antibodies are the most commonly recognized type of food allergy.[2] IgE antibodies are formed to soluble antigens that bind to antibodies, crosslink, and activate mast cell degranulation. Oral allergy syndrome is an IgE-mediated immune reaction; symptoms are usually limited to the oropharynx, which occurs upon ingestion of certain fresh fruits, nuts, or vegetables in pollen-sensitized individuals. The proteins in pollens and particular foods are similar in causing a reaction when particular raw fruits, nuts, or vegetables are eaten. Common symptoms include itching, tingling, erythema, and angioedema of the lips, mouth, and throat and usually occur within 5 minutes of eating the food. Cooked foods rarely induce the same response, because the protein shapes are changed when food is heated or digested.[49,50]

Type II

Type II sensitivity reactions involve IgG antibodies that are associated with cells or cell receptors. The antibodies alter signaling to the cell or affect the body through the complement system. Most often this reaction is seen in antibiotic or other drug reactions when IgG antibodies attach to red blood cells, causing destruction of red blood cells or platelets.[48]

Type III

Type III sensitivity reactions (Arthus reactions) involve IgG antibodies and soluble antigens. Normally, if an IgG antibody is produced and binds to its soluble antigen in large aggregates, the complement is fixed and the complex is readily cleared by the mononuclear phagocyte system. Small complexes are formed when there is a lot of antigen in the system; these complexes are often deposited in the blood vessels. These small complexes can bind to receptors on white blood cells, leading to white blood cell activation and tissue damage. A localized reaction is called an Arthus reaction and can be triggered in a sensitized individual

who has IgG antibodies against a particular antigen. When that antigen is injected under the skin, IgG antibodies induce a local inflammatory response in the skin, causing swelling and redness. Mast cells induce this response in the skin and in the linings of joints (synovial). This process happens in the lung epithelium induced by macrophages in the alveoli.[48] Pathologic immune-complex deposition is seen in situations where antigens persist, and when the body is not able to clear the complexes. This mechanism may be what occurs in subacute bacterial endocarditis or chronic viral hepatitis. The replicating pathogen continuously provides new antigens, and the body continues to form antibodies that result in these small complexes that deposit in blood vessels. Tissue damage can occur in a variety of tissues and organs, including skin, kidneys, and nerves.[48] Research has not been done to study antibody–antigen complexes that are formed when food is eaten continually in people with persistent IgG antibodies. This could be a possible mechanism for the food sensitivity reactions seen affecting people in a variety of tissues.

Type IV

Type IV hypersensitivity reactions are a delayed-type hypersensitivity (DTH) response that is mediated through T cells making T_H1 cytokines (interferon-γ, tumor necrosis factor-α, and tumor necrosis factor-β) rather than antibodies. Generally, soluble antigens are presented by macrophages to antigen-specific effector T cells. These T cells respond like they would to any pathogen causing a T_H1 cytokine reaction. The cytokines, chemokines, reactive oxygen species, prostaglandins, and leukotrienes formed by these T cells cause local and systemic tissue destruction. This type of reaction is being studied as a mechanism for atopic eczema.[51-54]

FOOD ALLERGY TESTING METHODS

The immune system has a variety of possible ways it can react that could induce a food allergy reaction. Different testing methods are best for specific food allergy reactions. There are variables within a testing method that may make its reliability and clinical relevance questionable. All of these factors need to be taken into consideration when selecting a food allergy testing method.

There are a variety of ways to test for food sensitivities, including elimination/challenge, skin testing, patch testing, enzyme-linked immunosorbent assay (ELISA) antibody tests for IgE, IgG, IgG4, and IgA antibodies, biochip technology, and energetic testing methods. As immunologic methods become more sophisticated, more specific and accurate tests are likely in the future. All methods look at a particular aspect of food reactions and have specific advantages and disadvantages. Clinical interpretation is required regardless of the type of testing used.

Elimination/Challenge

The most commonly used way of identifying and verifying food reactions is elimination and challenge of the specific foods. The double-blind, placebo-controlled food challenge is the gold standard for identification of food allergies and sensitivities for Western medicine.[55,56] Often the food is disguised to eliminate potential bias on behalf of the patient and is used to identify type I hypersensitivity reactions.[57] Many clinicians use food elimination and challenge as a way to confirm a food reaction. The basic design is to eliminate a suspect food for a period of time to see which symptoms subside. When the food is reintroduced to the diet, clinicians observe which symptoms reappear.[12,56]

Method: Eliminate test food or foods from the diet. This method depends on clinical presentation, ability of the person to adhere to a restricted diet, and preference of the clinician.

Eliminate:

1. A single suspect food.
2. A group of commonly allergenic foods (dairy, eggs, gluten, citrus, nuts/seeds, and shellfish, etc.) or a group of identified allergenic foods.
3. Most foods except those generally thought to be "safe." (Start eating one safe food only, add another if there is no reaction. Continue process.)
4. Water fast for a time to reduce allergenic symptom load before adding foods back to the diet.

Reintroduction: (Caution: This type of testing should not be conducted with foods that are known to induce severe or anaphylactic responses in a person.)

1. Add back one food every 3 days to diet.
2. Watch for any food sensitivity reactions to start.
3. If a reaction starts, wait until the symptoms resolve before trying a different food.

Type of reaction: This test has the potential to identify any type of food reaction causing physical symptoms, provided the person has the ability to recognize the physical symptoms when they occur. Because the test occurs in the person (in vivo) rather than with bodily fluid (in vitro), any type of immune response could show a reaction.

Advantages: This method identifies any type of reaction to foods and can be used to confirm a reaction and motivate food elimination compliance as well as identifying food sensitivities. The method is very adaptable and can accommodate a wide variety of people.

Disadvantages: This method is not appropriate for people with severe allergic reactions. People can influence the results based on their ideas rather than real reactions. The method can be time-consuming and requires the ability to be on a restricted diet. Also, some patients are not willing to stop eating favorite foods without an objective reason.

Clinical evaluation: Clinicians can consider the severity of the food allergy response, the timing and type of symptoms present, and past reactions when developing a specific, individualized protocol. The elimination/challenge diet can be used to confirm a food reaction as well as identify food allergies.

Skin Prick Testing

Skin prick testing (SPT) is the most common test performed by conventional allergists to confirm IgE-mediated allergies. This type of allergic response is typically seen in environmental allergic reactions, but can also be seen in food allergies.

Method: SPT is done by placing a drop of commercially prepared allergen on the skin and "pricking" or lightly lancing the skin. The person is allergic to the allergen when they have erythema or swelling greater than that of the control. This method identifies reactions to allergens that produce a type I, IgE-mediated allergy response.[58,59] Immunologically, the IgE antibodies that the body made from past exposure to the allergen are bound to mast cells that degranulate when the allergen is encountered during the test.

Advantages: SPT is more sensitive than radioallergosorbent testing (RAST), which is an in vitro test looking specifically for IgE antibodies. The test is very accurate for identifying environmental allergies.

Disadvantages: SPT requires that a person be exposed to the allergen before being tested, so the body can produce IgE antibodies.

A person cannot be taking antihistamines or other immune suppressants at the time of the test. Some food sensitivities are not IgE antibody mediated and therefore cannot be identified using this method. The commercial extracts used for SPT can degrade and vary by manufacturer.[60,61] Although some people react to specifically cooked or raw foods, commercial extracts may lack the ability to display the labile proteins involved.[62]

Clinical Evaluation: This test is usually performed by a board-certified allergist. People who report being tested for food allergies already have had their IgE-mediated food allergies tested through SPT. If there is no reaction with SPT, then the food reaction is almost certainly not IgE mediated (excellent negative predictive value).[24] Intradermal skin testing is a similar, more sensitive test and involves injecting the suspected allergen into the skin. This test is sometimes used by allergists when they suspect an allergy but had no response with SPT.

Atopy Patch Test

Atopy patch test (APT) is most commonly used to distinguish irritant contact dermatitis from allergic contact dermatitis. APT is used to identify allergies that take a few days to show up, also know as late-phase clinical reactions.[54] Irritant contact dermatitis does not have an immune response and is seen when a person is in contact with skin irritants such as household cleaners, paints, oils, adhesives, and cement.

Method: APT is performed by using adhesive tape to adhere particular potential allergens on the skin. The patches are left in place for 48 hours, and the skin is examined at 48 and 72 hours for a response. If the skin develops redness or blisters, the person is allergic to the substance.[63,64] This testing method identifies type IV hypersensitivity reaction, also known as DTH response. This type of immune response is mediated through T cells rather than antibodies and takes 2 to 3 days to show a response. APT is beginning to be explored in infants with atopic eczema as a way to discover food sensitivities missed by SPT and RAST testing.[65]

Advantages: APT offers a way to look at T-cell mediated reactions to foods. This type of test can be done in people taking antihistamines because it is not dependent on mast cell degranulation for a result.

Disadvantages: The research examining APT for atopic eczema is recent, yet the results appear promising.[64,66-68] Studies examining gastrointestinal diseases have had mixed results.[67,69] The patch test is performed most often with cosmetics, cleaning products, jewelry, and metals that come in contact with skin. Although most clinicians will use commercially prepared extracts, it is possible to make food extracts from fresh foods. This can be time-consuming and make interpretation more challenging. The test requires some skin that is not affected with a rash or eczema, and at least three visits to the doctor for application and interpretation.

Clinical Evaluation: APT is being used experimentally for atopic eczema, and is usually used in conjunction with other tests. A controlled, oral food challenge is still necessary to verify symptoms in reactive foods.[24]

Radioallergosorbent Testing

Radioallergosorbent Testing (RAST) was the first test reported in the literature for identification of IgE antibodies to specific allergens.[70] This test allowed the in vitro testing of allergies. Through the years, the specificity of allergens has changed and the method has developed considerably. The basic method of the RAST test is followed in different forms as the technology of antibody testing has evolved.

Method: RAST testing is performed using human serum to measure the amount of IgE antibodies present. In brief, the method involves binding a specific allergen to a solid substrate and adding human serum. Specific antibodies in the serum bind to the allergen. The serum is rinsed off, leaving the bound antibodies behind. A radioactive marker is added to bind to the IgE antibodies bound to the substrate. The radioactive signal can be measured and is proportional to the amount of allergen-specific IgE antibody in the serum. RAST identifies type I hypersensitivity reactions mediated by IgE antibodies.

Advantages: This type of testing allows for identification of allergens in the blood rather than using an SPT. RAST sets the stage for second-generation, allergen-specific antibody tests using the same basic method.[71] The newer antibody tests can measure different types of antibodies, use higher quality allergen extracts, and use different matrix substrates that improve the test accuracy and sensitivity.

Disadvantages: Antibody testing is limiting in that a person needs to be exposed to an allergen to have antibodies and a positive result. This type of testing specifically looks at only IgE antibodies and is hampered by cross-reactive proteins and low-quality test agents.[72,73]

Clinical Evaluation: RAST testing in its original form is not used currently. It has been replaced by quantitative, automated technology, bringing more accuracy and precision to this type of testing.[70]

Enzyme-Linked Immunosorbent Assay

Enzyme-Linked Immunosorbent Assay (ELISA) is a second generation, allergen-specific antibody test also known as a solid-phase immunoassay. The technology has advanced significantly since RAST was developed in 1961, allowing for a variety of changes in this type of testing. Most ELISA test results are reported qualitatively (positive or negative), or semi-qualitatively (values are assigned into different classes of reactivity).

Method: ELISA testing is similar to RAST in that an antigen (allergen) is bound to a solid substrate, and serum or whole blood is added to allow for antibodies to bind to the allergen being tested. The sample is rinsed to remove unbound antibodies and a fluorescent marker is added to bind to the desired antibody. ELISA tests can be used to identify IgE, IgG, IgA, and IgM antibodies depending on the fluorescent marker that is added. When measuring IgE antibodies, the test is looking at type I hypersensitivity responses. When measuring IgG, responses may be related to type II or type III hypersensitivity responses, although the significance of these responses to foods has not been fully elucidated. ELISA tests can be performed for whole blood (IgG, IgA, IgM), serum (IgE, IgG, IgA, IgM), saliva (IgA), and stool (IgA) samples.

Advantages: ELISA testing is versatile, relatively inexpensive, and readily available, making it a useful screening tool for food allergies. The clinical relevance of IgG antibodies to food is still being debated.[74,75] IgG testing is generally accepted in the literature for celiac disease and irritable bowel syndrome,[76] but not for other diseases.

Disadvantages: A person must be eating the food in question for it to come up positive on an antibody test. Without exposure to the food, the white blood cells do not get activated and make antibodies. More frequent exposure to specific food sensitivities induces higher antibody levels in reactive individuals. If a person stops eating the reactive food, the antibody response will initially increase, because the antibodies are still being produced, but not utilized. The amounts of antibodies will decrease over time as

long as the immune system is not reactivated by the food. Cross reactions between specific food antigens and other agents can cause a positive test reaction even when a person has never eaten the food. The significance of these types of cross reactions is generally unknown.

The quality and form of the antigen (food) being tested greatly affects the results. One research study looking at the differences between raw versus processed food allergens showed higher reactivity in processed foods.[77,78] Most commercially available antigens are made from raw foods, highlighting the importance of the type and quality of food antigen being used in testing.

Allergy shots are given specifically to induce an IgG antibody response to a food. If a person has received allergy shots as a treatment for an IgE-mediated allergy, the IgG antibody may be protecting them from a more severe anaphylactic response to that food.[70]

Clinical Evaluation: ELISA tests for IgG or IgA antibodies are often used by alternative medicine practitioners to identify food allergies that have not been identified with more conventional, but limited, methods examining IgE antibodies. People with a history of allergy shots or anaphylactic responses in the past should be monitored closely for an increase in IgE antibodies after food elimination, because IgG antibodies can increase as a protective mechanism in these people. If a person has multiple extremely high reactions to a variety of foods, it may be a nonspecific reaction to a test reagent rather than reactions to specific foods.[79] Testing total antibody levels can be instrumental in determining whether the person has a high antibody load or a nonspecific reaction to the test reagents.

Third Generation ELISA Assays

Third generation ELISA assays ImmunoCAP (Phadia, Uppsala, Sweden), Immulite (Deerfield, Ill.), and Turbo RAST (Hycor, Garden Grove, Calif.) are automated systems utilizing solid-phase immunoassay technology to identify IgE antibodies.[71,80-82] These systems are more sensitive and specific for IgE antibody tests than ELISA or RAST, although most of the research performed examined latex and other environmental allergens. Technologic advances have allowed quantification of IgE antibodies and calibration, so different tests could be compared.[70]

Method: The method is similar to RAST and ELISA testing but uses an automated machine and different solid substrates to increase sensitivity and specificity.

Advantages and Disadvantages: This technology improves on ELISA technology, but is more expensive and generally only available for IgE antibodies. These third generation of IgE ELISA tests improved on RAST by developing a dose–response curve of IgE. This allowed clinicians to study how the quantity of serum IgE antibody was related to clinical sensitivity by relating amounts of IgE antibody to the results of double-blind, placebo-controlled food challenges.[83,84] Dose–response curves have not been created for IgG, IgA, or IgM antibodies. The relationship between amount of non-IgE antibodies and clinical symptoms has not been correlated in research studies. Different systems cannot be accurately compared directly,[81] although, unlike IgG and IgA testing, there is literature comparing the different methods.[85,86]

Clinical Evaluation: For identifying specific IgE allergens, these methods are less sensitive than skin testing, but more sensitive and specific than ELISA testing. Serologic IgE antibody tests can aid in predicting the presence of clinically significant food allergies and can therefore decrease the need for food challenges.[84]

Microarray Chip Technology

Microarray chip technology (ImmunoCAP-ISAC [Phadia, Uppsala, Sweden]) is an IgE antibody technology that utilizes serum to identify IgE antibodies.[87] Recombinant proteins are used as a purified source of allergic proteins, allowing for specific identification of allergens.[88]

Method: Allergens are bound in triplicate to a microarray chip. Serum is added to the chip and antibodies specific for the allergens attach to the chip surface. IgE is detected with a fluorescently-labeled IgE and read to give a semi-quantitative estimate of amounts of IgE.[88]

Advantages and Disadvantages: This technology is being utilized to identify specific proteins in foods that a person reacts to. This may allow clinicians to correlate clinical reactivity with IgE antibodies to specific proteins in foods,[73] or identify them if cross reactivity occurs with foods carrying homologous proteins.[89-91] This type of testing could be easily adapted to identify IgE, IgG, IgA, and IgM antibodies in parallel.[88] More studies are required to fully understand the role of specific proteins in the severity and persistence of an allergy response.[92] Microarray tests are not considered as sensitive as the third generation ELISA tests (ImmunoCAP) tests when the same allergens are used.[82]

Clinical Evaluation: Identification of specific allergic proteins in foods could allow for greater correlation between antibody responses and clinical responses, and could allow for more specific immunotherapy.[92,93]

Energetic Methods

Energetic methods of food sensitivity testing (electroacupuncture according to Voll, Vega testing, Carroll testing, applied kinesiology, electrodermal screening [EDS], and bioresonance therapy) are some of the ways some alternative medicine practitioners test for food sensitivities or intolerances. They measure the energetic response to foods or other substances, such as medications, supplements, and hormones.

Methods: The methods of these types of tests vary and are generally not elucidated. Most appear to be measuring galvanic skin resistance through an electrical circuit.

Advantages and Disadvantages: Some practitioners have reported good success with these types of devices in identifying food sensitivities. Clinical trials using Vega testing and EDS have not shown them to be reliable compared with traditional allergy testing.[94,95] A review of applied kinesiology literature showed the studies to be unreliable, although many of the studies quoted in a review showed favorable results.[96]

Clinical Evaluation: Scientifically, energetic testing methods are unsupported in the literature. Some practitioners may still find these techniques to be useful tools, but they should not rely solely on this type of testing for diagnosis and treatment of food sensitivities.

Other Testing Methods

Other testing methods, including lymphocyte response testing (ELISA/ACT), cell size variability testing (ALCAT), provocation–neutralization testing, cytotoxic food allergy testing, and Nambudripad's allergy elimination techniques (NAET), have been used for food sensitivity testing and treatment. Anecdotal evidence is positive for many of these testing methods,[97,98] but systematic scientific studies have either not been done to verify the clinical relevance of these methods, or have shown the tests to be unreliable and clinically questionable.[74,99,100] Four review articles suggested

that these methods lack scientific rationale, standardization, and reproducibility.[101-104] Cell size variability testing had random results with the same sample in a study examining reproducibility and reliability of this testing method.[105]

THERAPEUTIC CONSIDERATIONS FOR FOOD ALLERGY TESTING

The list of food allergy symptoms is growing all the time. It ranges from traditionally accepted symptoms such as anaphylaxis and hives to less generally accepted symptoms such as headaches, diarrhea, fatigue, and joint pain. Food allergy tests can give clinicians good tools for developing a treatment plan for people with a wide variety of symptoms. Treatment of any type of food allergy or sensitivity is dependent on a variety of factors. A detailed medical history, physical examination, and laboratory tests must always be considered when choosing a food allergy test and interpreting the results.

When choosing which type of food allergy test to perform, consider the types of reactions the patient has had in the past. If there is any history of anaphylaxis or difficulty breathing associated with foods, then a test that evaluates a type I sensitivity response should be considered. ELISA testing for IgG antibodies (and possibly IgA and IgM) can be useful for a wide variety of symptoms. See Box 15-1 for a list of possible reactions. IgG antibody responses to foods are seen clinically,[6,106] but the relevance is still being debated in the scientific literature.[107-111] A person can have food sensitivity–related symptoms and not have any reactive foods on a test.

Many of the food allergy tests available are not standardized by the Clinical and Laboratory Standards Institute, so results between companies cannot be compared. Some tests are not internally consistent as well as not comparable to other laboratories, as shown in a small study that examined multiple samples sent to two different laboratories.[105] A clinician can test if a laboratory is internally consistent by sending to the same laboratory two samples from the same person and same blood draw, but under different names. The results should be nearly identical. This can also be done to test the accuracy of some of the energetic methods of food sensitivity testing. This can help the clinician be more confident in the reproducibility and consistency of the test results.

The relationship between non-IgE testing methods and disease is not well represented in the research literature. Clinicians are starting to recognize the importance of addressing food allergies when treating a variety of complaints. Food has a role in decreasing inflammation in the body and can be used to treat inflammatory diseases. The immune system has an extensive presence in the intestines, and by working with how the body accepts food, oral tolerance could be restored with implications in many disease processes (see Box 15-1).

CONCLUSIONS

Food allergy tests should be used in clinical practice to confirm or exclude a suspected diagnosis of food allergies and as a tool to motivate dietary changes. Selection of allergy diagnostic tests and interpretation of the results must be directed by the person's clinical history. Future research studies should address the clinical significance of IgG, IgA, and IgM antibodies to specific foods and correlate physical symptoms with food allergy elimination. Food can be medicine in chronic illnesses when food causing inflammation is eliminated from the diet. Diagnosing food-related illness will become easier as food allergy diagnostic methods continue to improve.

BOX 15-1 Food Sensitivity Reactions

- **Skin reactions:** Itching, burning, hives, red spots, sweating, eczema, psoriasis, other rashes.
- **Ear, nose, and throat:** Sneezing, runny nose, sore or dry throat, hoarseness, ringing in the ears, dizziness.
- **Eyes:** Blurring, spots before eyes, watering, pain, twitching, sensitivity to light, redness, swelling of eyelids.
- **Respiratory:** Wheezing, mucus formation, shortness of breath, tightness of chest, asthma.
- **Cardiovascular:** Pounding heart, increased heart rate, flushing, tingling, faintness.
- **Gastrointestinal:** Increased salivation, canker sores, indigestion, bloating, stomachache, heartburn, colic, constipation, abdominal pain, diarrhea, gas, itching, or burning of rectum or anus. One may also experience weight gain from food sensitivities.
- **Genitourinary:** Frequent, urgent, or painful urination; inability to control bladder; itching; discharge; pain; water retention.
- **Musculoskeletal:** Fatigue, weakness, pain, swelling, stiffness of joints, backache.
- **Nervous System:** Headache, migraine, drowsiness, inability to concentrate, depression, irritability, restlessness, hyperactivity, dizziness, numbness, tremors.

This list is just a partial list of symptoms that may respond to eliminating food allergies or sensitivities. Many of these reactions have a variety of possible causes and should be evaluated according to the clinical picture presented. Some reactions may be nonimmune mediated and not test positive on a food sensitivity test.

INTRODUCTION

About 3 billion years ago, the experiment known as "life" began on Earth. All living creatures from the five kingdoms are descended from a single common ancestor. We know that all creatures on this planet are related to one another because we all share the same digital "language of life," known as DNA and RNA, made from five simple nucleic acids, connected along a sugar phosphate chain. If we could meet our primordial progenitor, we might not recognize it as living at all. We suspect it was nothing more than an RNA receptor-catalyst that somehow replicated itself by consuming chemicals in its immediate environment. These simple "ribo-organisms" were inherently unstable, forming and falling apart quite easily. Only over hundreds of millions of years did these organisms gain more stability when single-stranded RNA evolved into double-stranded DNA, and even more stability when the DNA began coding for proteins that would eventually evolve into cellular structure.[1]

Inherent in this narrative is a central fact that is easy to overlook: life began and continues to evolve within specific environments. We all know the classic riddle, "Which came first, the chicken or the egg?" From the perspective of evolutionary biology, this is not much of a riddle because the chicken's ancestors and their eggs preceded the arrival of the chicken by at least 100 million years. However on closer reflection, the riddle asks a far deeper and more perplexing question, "What is the relationship between the individual and its environment, between the chicken and its egg?" A hospitable environment had to precede the development of life, and no new life can evolve unless there is an environment to support it, but environments change over time, and a species must change to accommodate the new changes in its environment or invariably become extinct, as the vast majority of species that have lived on this planet have done. The central premise of Charles Darwin's grand theory of the origin of species speaks of survival of the fittest, but over time the fittest species is the one that can adapt best to a changing environment. Adaptation is not exclusive to the development of new species, but also plays a critical role in the survival of any individual within a species as well.

The twenty-first century may well be remembered as the century in which science first truly began to understand the complex interaction between the genetic information inherent in every individual and the environment to which that individual is exposed.

GENES AND ENVIRONMENT—NATURE AND NURTURE

"Environment" is broadly understood in genetics to include everything that is not the genetic information, or genome, itself. Environment includes climate, physical surroundings, exogenous chemicals or toxins, and infectious agents, but it also includes diet, lifestyle, and behavioral factors. Scientists once believed that genes were immutable archives of digital information that simply coded for proteins, which in turn determined the structure and function of an individual's (analogue) body. However, it is now irrefutable that gene expression is substantially affected by and sensitive to environmental change. Genes quite literally respond to the environment to which they are exposed.[2] Because genes respond to the environment we subject them to, the environment itself can be proactively manipulated to alter gene expression, and therefore, to change the health state of the individual. This is the central premise of preventive or functional genomics.

In the interactive symphony between genes and environment, the balance between the two may be altered whenever either changes. Because the environment is inherently unpredictable, one effective strategy to increase the chances of survival has been promoting genetic variation within a species, because slightly altered individuals may survive environmental change, whereas others may not. It is rather like a strategy for winning a lottery: odds of winning increase linearly with the greater variety of numbers that one is able to choose. Variety may truly be the spice of life. If populations from a single species diverge into different environments, the selective pressure over time may eventually lead to the creation of separate species.

The human genome is composed of approximately 3 billion nucleotides of genetic code. If you compare your DNA with the next person you happen to meet, you would find that about 1 in every 1000 nucleotides are different. That means that there are 3 million reasons why the two of you are not the same. These subtle variations of the genetic code are known as polymorphisms (literally, "many shapes," because if the change in the genetic code results in an amino acid substitution, the resulting proteins will have different shapes and slightly altered functions as well). It is these polymorphisms that are largely responsible for our biochemical individuality. Our polymorphisms help make us unique individuals. There are many types of polymorphisms, but by far the most common is the single-nucleotide polymorphism (abbreviated SNP and pronounced "snip"), in which a single nucleotide of the DNA is altered. The sum total of all of an individual's polymorphisms significantly affects protein synthesis and physiologic function, rendering each individual biologically and biochemically unique.

WHY DO POLYMORPHISMS EXIST?

The theory of natural selection has two central tenets: (1) all organisms compete for limited resources, and (2) organisms with some advantage in acquiring those resources are more likely to survive, to thrive, and to pass on that advantage to their offspring. Polymorphic variations are the ultimate source of these advantages. All polymorphisms that are found to be common in a species must afford some adaptive advantage to survival in some specific environment. Genetic polymorphisms are preserved and become more prevalent in a species when they endow a better chance of survival or of reproduction. The cumulative weight of slight genetic variations over time is the means by which variability within a species arises and by which new species also emerge. However, what may be good for a species and its evolution may not be good for a specific individual, because the environmental pressures exerted on a species over millions of years may be very different from the environment encountered in the present.

In individuals, altered polymorphic genes (the legacy of evolution) produce altered proteins, and altered proteins exhibit altered functions. For any given individual, altered protein function may be beneficial, neutral, or harmful, depending on the environment to which he or she is exposed. Prevalent polymorphisms are likely to be beneficial in certain environments but harmful in others. Because we cannot change our genes, the goal of preventive genomics is to alter an individual's environment based on his or her specific genetic variations to optimize his or her genetic potential. Genes themselves cannot be modified, but gene expression can be. One of the common misconceptions of polymorphisms is that they reveal only limitations, but in reality, they reveal an individual's potential.

NUTRIGENETICS AND NUTRIGENOMICS

From a clinical perspective, changes in diet are one major way of altering the gene–environment balance and improving an individual's health. Two distinct but interrelated fields of inquiry and knowledge are emerging. Nutrigenetics, also referred to as personalized nutrition, is based on the understanding that our genetic polymorphisms change the way we respond physiologically to specific nutrients. By studying specific polymorphisms and their physiologic response to specific nutrients, we can determine a more optimal nutritional regimen for a specific individual based on his or her specific polymorphisms. Nutrigenomics, by contrast, focuses on the effects of specific nutrients (both macro and micro) on the genome as a whole, and subsequently on the body's resulting total pool of proteins (the proteome) and on all its subsequent metabolic activity (the metabolome) as well.[2,3]

Food is, by definition, derived from other living organisms. Inherent in any food is an information code that we read and interpret by eating that food. There is a literal exchange of information that passes between the eaten and the eater. Not surprisingly, central to life is our ability to coordinate our metabolic activities with nutrient availability. Signals from the exterior world (food, toxins, weather, stress, etc.) turn on and turn off specific metabolic processes to improve our chances of survival in an ever-changing world.[4]

The most extreme example of the interaction of food availability and metabolic change is the situation, common in nature, when no food at all is available, i.e., famine. Clive McCay at Cornell University in the 1930s found that by restricting calorie intake in rats by at least 25% from the free-feeding level, he could substantially increase their average and extreme life expectancies, delay the age of tumor onset, delay cessation of reproductive function, and preserve functional homeostasis or stress response capacity.[5] Since that time, no major investigation has failed to demonstrate significant benefits to health and longevity from calorie restriction. Calorie restriction lowers the level of insulin exposure, which in turn lowers the overall growth factor exposure, improves age-declining maintenance of mitochondrial function, and helps to maintain a long-term favorable balance of the insulin-to-growth hormone antagonism.[6] From an evolutionary perspective, this makes intuitive sense. Only when calories are abundant does an individual have the metabolic resources for growth and reproduction. Survival during times of famine necessitates metabolic shifts that conserve resources and promote repair, because growth is not an option.[7]

Reducing calorie intake not only lowers overall insulin exposure but is now known to activate the transcription of a family of genes known as sirtuins (SIRT). The SIRT enzymes appear to have first arisen in primordial eukaryotes, possibly to help them cope with adverse conditions, like famine, and today are found in all plants, yeast, and animals. In response to calorie restriction, SIRT-1 stimulates the production of new mitochondria in skeletal muscle and liver cells, thereby increasing the capacity for metabolic repair and energy production. New mitochondria produce fewer free radicals than the old mitochondria, which leads to less free-radical damage and to delayed onset of metabolic aging. SIRT-1 also has a cascading effect on multiple genes, leading to increased catalase activity, increased free fatty acid oxidation for energy, and reduced inflammation via suppression of the enzyme nuclear factor-κβ (NF-κβ).[8]

The obvious problem with calorie restriction, however, is that we like food. Recent studies on the effects of the polyphenol compound resveratrol (initially isolated from grape skins) on obese,

sedentary mice, suggested that it could mimic the beneficial health effects of calorie restriction even while the rats continued to eat a high-calorie, high-fat diet and did not exercise. Dietary supplementation with resveratrol was found to oppose the effects of the high-calorie diet in 144 of 153 altered biochemical pathways, most of which could be attributed to its activation of the transcription of the enzyme SIRT-1. Resveratrol increased insulin sensitivity, reduced insulin-like growth factor-1 production, increased adenosine monophosphate activated protein kinase, increased peroxisome proliferator-activated receptor-coactivator-1 (PPAR-1) activity, increased the number of mitochondria, and improved overall motor function.[9] Such research suggests that at some future time we just may be able to have our cake, eat it too, and suffer few of the metabolic consequences for overeating. Nevertheless, the best current nutritional advice for longevity and health remains simply, "eat less." Not only does it lower insulin load, but it activates the transcription of numerous enzymes that promote mitochondrial regeneration, health, and longevity.

Not only is nutrigenomics helping to elucidate the myriad effects of specific nutrients on our genome, but it is also helping us rethink and understand the mechanisms by which other nutrients act on our physiology. *Ginkgo biloba* is a commonly prescribed medicinal herb that is known to increase peripheral microcirculation and to contain rather potent antioxidants. The vasodilation allows delivery of these antioxidant compounds to poorly vascularized areas, like the brain. Not surprisingly, ginkgo is commonly used for impaired memory and mental function as we age. Using gene chip assays, researchers examined cellular extracts to look for altered levels of messenger RNA, an accurate measure of gene activity. In vitro studies with human bladder cancer cells that were incubated with ginkgo resulted in suppression of gene transcription by more than 50% in 16 genes and induction of 139 genes by more than 100%. The overall effect of adding ginkgo was to activate genes that code for improved mitochondrial function and antioxidant protection. Subsequent in vitro mouse studies showed activity of more than 12,000 genes and a preferential activation of genes within the brain with induction of more than 200% of 43 genes in the cortex and 13 genes in the hippocampus, including those genes that promote nerve cell growth, differentiation, regulation, and function, as well as increased mitochondrial activity and antioxidant protection.[10]

This elegant research points to a new understanding of why and how herbal medicines or other specific nutrients can act to change our physiology, but also helps to explain why specific herbs or nutrients act preferentially on specific tissues or organ systems. It is not just *Ginkgo biloba* that acts to alter gene transcription. Every medicinal herb, every nutrient, every food, and every pharmaceutical medicine is likely to act in a similar fashion. These compounds do not just have a gross chemical effect on our physiology, but they actually alter gene expression. Nutrigenomics is forcing us to rethink the ways in which our bodies respond to environmental stimuli in the form of food, herbs, or medicine.

In some areas, nutrigenomics and nutrigenetics can overlap. We propose the use of the term "preventive genomics" to include both nutrigenomics and nutrigenetics because they cannot always be easily separated. To illustrate, PPAR-γ is a nuclear hormone receptor that regulates many cellular functions, such as nutrient metabolism, cell proliferation, and cell differentiation in response to dietary macronutrients, specifically to carbohydrate and fat intake. PPAR-γ integrates the cellular control of energy, lipid, and glucose homeostasis. Its activation by increased dietary fat or sugar intake is clearly an example of nutrigenomic interaction. However, there is a common polymorphism in the gene that codes for PPAR-γ in which at the twelfth amino acid in the protein, an alanine is substituted for a proline (the polymorphism is referred to as PPAR-γ P12A). Individuals with the 12A variant display a greater metabolic tolerance to a high-fat diet, leading to a significantly reduced risk of developing insulin resistance, type 2 diabetes, coronary artery disease, and central obesity when consuming a typical Western diet.[11] Individuals with the 12P variant are more sensitive to the ill effects of excessive dietary saturated fat intake, suggesting a clear therapeutic dietary strategy in P allele carriers to prevent obesity, diabetes, and heart disease.[12]

There are many polymorphisms like the PPAR-γ proline variation that exist in a large percentage of the population and appear to increase risk of certain serious diseases. They beg the question, why do these seemingly harmful polymorphisms exist? It is important to remember that the PPAR-γ proline variation is only harmful in individuals who eat a high-calorie, high-saturated fat typical Western diet. It behooves us to remember that in most of nature and for most of human history, too much food to eat was rarely a major risk factor. Quite the opposite was true when winter and famine were common occurrences. In these environments, the ability to extract more nutrition from the same caloric intake would be a distinct advantage for survival. It is only in the last 50 to 100 years in our culture of affluence that these variations have begun to pose significant risks to our health. We call these genes, "thrifty genes," a term first coined by D.L. Coleman to explain why the Pima Indians from the desert of the American southwest were prone to develop obesity and diabetes. Thousands of years of survival in that harsh environment selected for genes that made this group incredibly efficient at retaining calories from food—a distinct adaptive advantage when food supply was scarce. However, with the 24-hour grocery only a car ride away, their genes are significantly less well adapted to survive.[13] We see similar gene variations that increase inflammation throughout the body. This seems counterproductive until we realize that infectious disease has been a major environmental risk throughout evolution, and inflammation and immune activation are essentially the same biological process. It is imperative to remember that every polymorphism that exists in humans with significant prevalence confers protection and advantages to survival in some environment. Our task as clinicians is to identify that environment and to recommend it to those patients with that particular genetic variation.

NATURE VERSUS NURTURE

The reality is that the prevention and cure of complex diseases and syndromes are not to be found exclusively in our genes or our environment, but in the interactive symphony between the two. Nature (our genes) provides a plastic template that is largely adaptable to a wide range of environments ("survival of the most adaptable"), and slight variations in those genes can cause altered responses to specific environments (nutrigenetics). In contrast, nurture (our environment) switches genes on and off, largely controlling gene expression (nutrigenomics).

To illustrate this idea of gene–environment interaction, consider the research of Caspi et al.[14] They studied variations in the promoter sequence for the gene coding for monoamine oxidase-A (MAO-A) and found that a promoter polymorphism caused some people to have high-activity MAO-A genes and others to have low-activity genes. Those with high activity MAO-A would deactivate catecholamine neurotransmitters, like dopamine and noradrenaline, more rapidly. They then examined whether these genes played a role in antisocial and violent behavior in men who had been abused as children. Remarkably, they found that men with

the high-activity MAO-A gene were virtually immune to the effects of maltreatment as children, seldom if ever becoming violent offenders, whereas men with the low-activity MAO-A gene were much more antisocial and violent, but only if they themselves were abused as children. In other words, for violent behavior to manifest in adulthood, both the low-activity gene (nature) and childhood maltreatment (nurture) needed to be present. If either was missing from the equation, the adult was very likely to be well socialized and nonviolent.

The Centers for Disease Control and Prevention (CDC) published a *Gene-Environment Interaction Fact Sheet* in August 2000[15] that outlined the basic principles of a broad understanding of the causal interaction of genes and environment in human disease. In it, the CDC makes the following four main points:

1. Virtually all human diseases result from the interaction of genetic susceptibility and modifiable environmental factors.
2. Variations in genetic makeup are associated with almost all disease.
3. Genetic variations do not cause disease but rather influence a person's susceptibility to environmental factors.
4. Genetic information can be used to target interventions.

In this brief paper, the CDC essentially outlined the chief tenets of nutrigenetics and of preventive genomics.

Ironically, these ideas are hardly new. In 1909, Archibald Garrod[16] published *Inborn Errors of Metabolism,* in which, after identifying the first human disease that behaved as a true Mendelian recessive trait (alkaptonuria), he went further to construct a sweeping hypothesis that altered heredity was "the seat of chemical individuality." "Inborn errors of metabolism," he wrote, "are due to a failure of a step in the metabolic sequence due to loss or malfunction of an enzyme." By examining the subtle end products of metabolism, he continued, we should be able to identify the differences that altered heredity produces in each individual. This is a remarkable insight, given that the words gene and genetic did not exist in 1909, and it would be roughly 50 years before the structure and true function of DNA were confirmed. Moreover, Garrod's book was published 3 years before the first vitamin was discovered, so he would have had no notion of vitamins as cofactors in enzymatic reactions. He concluded his prophetic work by envisioning the complex interaction between our unique genetic constitution and environmental factors in the exquisitely simple statement "These idiosyncrasies may be summed up in the proverbial saying that one man's meat is another man's poison."

THE CLINICAL UTILITY OF NUTRIGENOMICS AND NUTRIGENETICS

The point of using genetic and genomic information in a clinical setting is to personalize the therapeutic regimen and to develop an effective strategy towards true disease prevention. It is a common mistake, however, to think that somehow the new preventive genomic information we can access will make all previous therapies obsolete. This is evident in the mindset that thinks we can attribute disease risk to polymorphisms without reference to environment (read any genetic newspaper headline). Simply put, genetic information is no more and no less valuable than environmental information. We need them both to make an optimal difference. Furthermore, at this stage in preventive genomic research there are at best only 100 or so polymorphisms about which we have sufficient clinical information to make personalized nutritional recommendations.[17] It is useful information, to be sure, but it is insufficient for comprehensive nutritional and therapeutic recommendations.

Carl Sagan once said, "If you want to make an apple pie from scratch, you must first create the universe." Fortunately for making an apple pie, the universe has already been created, and fortunately for making comprehensive nutritional recommendations, natural selection has been active since the beginning of life on this planet. As humans, we and our ancestors have been adapting to environments for the last 3 billion years, if you want to think of all life, or for a mere 600 million years, if you want to think of eukaryotic cells with aerobic respiration. Either way, it is a lot of experimental trial and error that brought us to the present. The proper starting point of nutrigenomics and nutrigenetics is not genetics per se, but good epidemiology. Good epidemiology can tell us what is the best nutrition and lifestyle for the average person. Specific genetic polymorphisms can help us modify these recommendations to meet the specific genetic needs of an individual patient.

Discovering the optimal nutrition and lifestyle for a specific individual will depend on developing a functional matrix that is minimally composed of:

1. Good epidemiologic dietary and lifestyle data
2. Specific genomic polymorphisms that alter specific macronutrient and micronutrient requirements
3. Functional laboratory assessment of individual function, physiology, and micronutrient status

In terms of Western diets, the Mediterranean diet is one of the best studied and, which, from an epidemiologic perspective, is arguably the best for disease prevention and optimal health. It has been demonstrated to reduce cholesterol and triglycerides, to prevent atherosclerosis and high blood pressure, to reduce the risk of senility, stroke, heart disease, insulin resistance, type 2 diabetes, and numerous cancers, including those of the breast, prostate, and colon.[18] Among elderly Europeans, a Mediterranean diet combined with moderate daily activity and no smoking reduces all-cause mortality by 67%, and switching to this healthier diet and lifestyle at age 70 reduced mortality rates by 50%.[19]

Clearly, these results are impressive, but the central tenet of preventive genomics is that these risks can be reduced further with the judicious application of nutrigenetic information gathered from the analysis of individual polymorphisms. Not all polymorphisms are clinically relevant. Most of our interindividual genetic variation occurs in sections of the DNA that do not actually code for proteins. About 97% of our DNA is either of viral origin, repeats, or simply junk DNA that codes for nothing. To make genomic information clinically useful, polymorphisms must meet four essential criteria: they must be relevant, prevalent, modifiable, and measurable.

1. First, the only polymorphisms in the genome of clinical interest are those that exert an effect on some specific aspect of our biochemistry and physiology (relevant).
2. Second, given our current knowledge of the human genome, only polymorphisms that exist in a substantial portion of a population are likely to be able to be demonstrated in epidemiologic and case-controlled studies to be clinically relevant—in essence, we compare polymorphisms that occur in substantial numbers in both groups (prevalent).
3. Third, only polymorphisms whose genetic expression is modifiable via reasonable clinical intervention are clinically useful. Such an intervention may be any modification of environment, including diet, lifestyle, and targeted nutraceuticals or pharmaceuticals. Although genes themselves are not modifiable, the phenotype they generate is modifiable via environmental changes because environment turns genes on and off.

4. Finally, because our genes do not themselves change, we must be able to measure changes in our functional physiology to determine that the environmental changes implemented have been effective in modifying the phenotypic or physiologic expression of our unique genes. For this purpose, functional testing must be available and used in conjunction with genomic testing for polymorphisms (measurable).

To illustrate this model of clinical utility, let us consider the example of the detoxification and antioxidant protection afforded by the enzyme glutathione-S-transferase (GST). High levels of toxins and oxidative stress are associated with numerous degenerative diseases and with the aging process itself. So an enzyme like GST that protects against such oxidative damage is highly relevant to our health. The GST polymorphisms have been associated with numerous cancers in epidemiologic and case-control studies.[20] Although there are several isoforms of GST in the body, the μ isoform, GSTM1, is the most common in the liver. Fifty percent of the population does not have any copy of the GSTM1 gene, so clearly it is prevalent. Because other isoforms of GST and other antioxidant pathways exist, it is possible to improve antioxidant protection by maintaining a high reduction potential through exogenous avenues, including dietary antioxidants. Furthermore, men and women who lack the GSTM1 gene all together can increase their serum glutathione levels by 16% and 38%, respectively, and their other GST activity by 6% and 8%, respectively, simply by eating four or more servings of brassica vegetables weekly. Interestingly, individuals possessing a GSTM1 gene showed significantly less benefit.[21] Similar benefits were seen from regular brassica vegetable consumption in reducing colorectal cancer by 53%[22] and lung cancer in smokers by 70%,[23] but again only in individuals lacking the GSTM1 gene. Thus, the increased oxidative stress is attenuated by regular brassica vegetable consumption. Finally, we can validate the clinical efficacy of our intervention strategy by measuring functional levels of oxidative stress through any number of simple laboratory tests, such as urine lipid peroxides, 8-hydroxy-deoxyguanosine, serum glutathione, urine, or plasma cysteine/cysteine ratio, etc. The biological effects of our interventions are measurable.

Personalized Nutrition and Nutrigenetics

Currently, most of the clinically relevant nutrigenomic information available relates to the relationship between polymorphisms with increased chronic disease risk and the dietary therapies and supplements that have been demonstrated to treat the physiologic imbalance effectively. This is particularly true of SNPs. In as many as one third of genetic polymorphisms, the corresponding enzyme has a decreased binding affinity for a vitamin or mineral coenzyme, resulting in a lower rate of reaction and altered enzyme function. In a review article, Ames et al[24] provided evidence of more than 50 human diseases involving defective enzymes that could be remedied or ameliorated by the administration of higher doses of vitamins or minerals, which at least partially restore enzyme activity. Thus, the clinical validity of high-dose nutrient therapy is established, but only in genetically susceptible individuals.

CLINICAL APPLICATION OF NUTRIGENETICS

The Example of Cardiovascular Disease

Cardiovascular disease accounts for approximately 40% of all deaths in most industrialized countries and is also responsible for significant morbidity and diminished quality of life. Furthermore, using data from more than 84,000 women who were monitored for 14 years, epidemiology researchers at Harvard University estimated that about 83% of cardiovascular disease could be decreased if everyone ate a reasonably healthy diet, exercised daily, did not smoke, maintained a normal weight, and drank 1 to 2 alcoholic beverages per day.[25] Although these five diet and lifestyle changes seem fairly simple, only 3.1% of the women in the study actually adopted them. Not only is compliance an issue, but epidemiologic studies raise deeper philosophical questions, because such studies assume that all participants are essentially similar to one another. Are the same therapies equally effective for all individuals? Do all individuals need the same quantities of these diet and lifestyle modifications? Can preventive genomic testing help us individualize our therapeutic protocols?

Let us begin by asking what proportions of carbohydrate, protein, and fat in the diet are the most effective in maintaining normal serum cholesterol levels. Is it a low-fat, low-cholesterol diet as touted by Nathan Pritikin and Dean Ornish? Or perhaps a 40-30-30 (40% carbohydrate, 30% protein, 30% fat), low-calorie "Zone" diet as proposed by Barry Sears? Or a low-carbohydrate, high-protein, high-fat diet such as that made popular by Robert Atkins? Logically they cannot all be the best diet for everyone, yet some people swear by each of them as the answer for an optimal diet.

There is mounting evidence that optimal macronutrient proportions in the diet may be a function of specific polymorphisms. Apolipoprotein-E (Apo-E) is a molecule that mediates the interaction of chylomicron remnants and intermediate-density lipoprotein particles with lipoprotein receptors, including the low-density lipoprotein (LDL) receptor and the chylomicron remnant or Apo-E receptor. There are three variations of the Apo-E gene, known as Apo-E2, -E3, and -E4, and these polymorphic variants are important genetic modifiers of serum lipid responses, which consequently may significantly affect an individual's risk for development of coronary artery disease. (Technically, each of these polymorphisms is a haplotype: two individual SNPs at different points in the Apo-E gene that are linked.) The E3/E3 genotype is the most common in all populations and serves as the benchmark genotype for comparison with any other possible genotype. The E4 allele is associated with a moderately increased risk of atherosclerosis and coronary artery disease (odds ratio [OR] = 1.53 for men and 1.99 for women in one study).[26] The E2 allele is associated with lower LDL cholesterol levels. LDL cholesterol levels declined with each Apo-E2 allele by 8.8 mg/dL in Hispanics, by 25.6 mg/dL in non-Hispanic white persons, and by 18.1 mg/dL in African-Americans.[27]

Given that each person inherits two alleles, there are six possible genotypes: E2/E2, E2/E3, E3/E3, E2/E4, E3/E4, and E4/E4. In patients with elevated serum total and LDL cholesterol, the cholesterol-lowering response to a low-fat, low-cholesterol diet increased as the sum of the allele numbers increased (in other words, response improved in the order that the genotypes are listed in the first sentence in this paragraph).[28,29] Conversely, individuals carrying an E4 allele who ate a high-fat diet were much more likely to have elevated serum cholesterol.[30]

In contrast, serum triglyceride levels were found to be significantly higher in men, and to a lesser extent in women who carried an E2 allele. Moreover, the triglyceride levels of individuals with an E2 allele showed a dose-dependent relationship to table sugar consumption, an association not shared with the other genetic variations.[31] Dietary sucrose consumption also increased very low-density lipoprotein (VLDL) cholesterol and triglycerides in Apo-E2 carriers. In contrast, E3/E3 individuals were found to have the lowest triglyceride levels, and E4 carriers to have intermediate levels.[32] In another multiethnic study, plasma triglyceride levels were inversely correlated with the number of Apo-E4 alleles (175, 159,

and 143 mg/dL with 0, 1, and 2 alleles, respectively).[33] Another study found E4 carriers to have elevations in triglycerides, but only those who consumed alcohol regularly.[34] A study of Turkish men who did not consume alcohol found no elevated triglyceride values in E4 carriers.[35] The most effective dietary therapy to lower triglycerides is restricting carbohydrate, especially sugar, consumption. Because Apo-E2 men are prone to significant triglyceride elevations and their levels are less sensitive to dietary fat intake, a lower carbohydrate, higher protein, higher fat diet may be therapeutically desirable for them.

Individuals with the E3/E3 genotype are moderately affected by dietary fat intake but tend to have lower triglyceride levels than the other genotypes. In one study, individuals with high cholesterol and triglyceride values were treated with a short-term (7-day) very low-calorie juice fast (208 calories/day), and their responses were stratified by Apo-E genotype.[36] Only E3/E3 individuals experienced significant improvement in all parameters, experiencing reductions in LDL cholesterol by 10% and in triglyceride values by 18%. In these individuals, it is tempting to speculate that the low-calorie, moderate 40-30-30 carbohydrate-protein-fat ratio "Zone" diet might be more effective in treating both hypercholesterolemia and hypertriglyceridemia, although no clinical trials to validate this hypothesis have yet been published. Also, in this trial, E2 carriers experienced a 31% drop in LDL levels but a 15% increase in triglyceride levels, lending some additional support for the carbohydrate-sensitive triglyceride hypothesis. E4 carriers had an opposite response to E2 carriers: a dramatic reduction of triglyceride levels by 49% but a rise in LDL levels by 13%, while eating only 200 calories/day.

Other dietary interventions that affected cholesterol levels were fiber and alcohol. High intake of soluble fiber (5.7 g/day) reduced LDL cholesterol by 6.6% and 5.6%, respectively, in E3 and E4 allele carriers but had little effect on E2 carriers.[37] Similarly, a study of Korean patients with coronary artery disease found that replacing white rice with whole grains produced the greatest benefit in E3/E3 individuals (12% reduction in triglyceride, 8% reduction in LDL cholesterol, and 8% increase in high-density lipoprotein [HDL] cholesterol levels), as well as moderate benefit in E4 carriers (including a 15% increase in HDL cholesterol values), but there was absolutely no effect on cholesterol levels in E2 carriers.[38] Thus, a high-fiber diet may be clinically most useful for E3/E3 individuals, modestly useful for E4 carriers, but not useful for E2 carriers.

The modest consumption (1 to 2 drinks) of alcohol daily has been shown epidemiologically to be extremely protective against coronary artery disease in the general population. However, Apo-E genotyping reveals that the benefits are not the same for everyone. In a comparison of nondrinkers with drinkers of alcohol, women who were drinkers had lower cholesterol (total and LDL) than women who did not drink, regardless of Apo-E genotype. In men, however, Apo-E2 carriers who were drinkers had lower cholesterol but Apo-E4 carriers had higher cholesterol, and alcohol consumption had no significant effect for Apo-E3/E3 individuals.[39]

It is worth observing that moderate exercise, although not dietary therapy, was found to be effective in improving serum lipids in E2 and E3 genotypes but not in E4 carriers.[40] In another study, high-intensity physical exercise was most effective in E4 carriers.[41] Thus, E2 and E3 carriers may benefit from modest daily exercise, but for an individual with an E4 allele to benefit from exercise, it must be high intensity.

Similarly, knowledge of Apo-E genotype may allow for a more discriminating and more effective use of targeted pharmaceuticals for patients with lipid abnormalities. Statin drugs exhibited a greater cholesterol-lowering effect in Apo-E2 carriers, followed by Apo-E3/E3, with less effectiveness for Apo-E4 carriers. Apo-E2 carriers also showed better response to gemfibrozil and cholestyramine than the other genotypes. The greatest cholesterol-lowering effects for Apo-E4 carriers came from probucol, a potent antioxidant.[26] However, although statins had a weaker cholesterol-lowering effect in Apo-E4 carriers, statins were most protective in preventing a second heart attack in men with an E4 allele. Statin use reduced the risk of a second heart attack in E4 carriers by 64% compared with only 33% for other genotypes, despite the fact that statins reduced LDL cholesterol levels least in Apo-E4 genotypes.[42]

TABLE 16-1 **Lipid-lowering Therapies Stratified According to Apolipoprotein-E (Apo-E) Genotype**

	Genotype*		
THERAPY	**E2/2 OR E2/E3**	**E3/E3**	**E4/E3 OR E4/E4**
Diet	Lower carbohydrate	Low-calorie, moderate-fat	Low-fat, no cholesterol Soluble fiber
Alcohol intake	Daily (women and men) (little effect for men)	Daily (women) None (men)	Daily (women)
Exercise	Moderate	Moderate	High-intensity
Pharmaceutical/ nutraceutical	Bile sequestrants Statins	Statins	Probucol Statins

*The E2/E4 genotype is extremely rare and therefore lacks statistical power in both association studies and prospective trials.

More prospective clinical trials are needed to fully elucidate the optimal therapeutic dietary interventions to protect against coronary artery disease in individuals based on their Apo-E genotype status. However, distinct patterns are beginning to emerge in terms of dietary and lifestyle management for the treatment of coronary artery disease; these are summarized in Table 16-1.

Apo-E polymorphisms are the best studied in terms of their association with atherosclerosis and coronary artery disease, but other polymorphisms exert similar effects. Cholesteryl ester transfer protein (CETP) is responsible for the transfer of insoluble cholesteryl esters from HDL to other lipoproteins.[43] The Taq1B polymorphisms of the CETP gene result in increased CETP levels, with impaired ability to remove cholesterol from the cells and the blood stream. The Taq1B polymorphism occurs with lower HDL cholesterol levels and an increased risk of development of atherosclerosis and coronary artery disease.[44,45] In one study, individuals who were homozygous for the Taq1B polymorphism had larger reductions in LDL and VLDL levels through eating a low-fat diet with a high ratio of polyunsaturated to saturated dietary fat.[46] Furthermore, daily moderate alcohol consumption raised HDL levels substantially, but only in individuals with the CETP polymorphism.[47,48]

E-selectin (SELE) is a glycoprotein molecule that adheres circulating neutrophils to the endothelial lining of blood vessels. E-selectin is expressed on the surface of endothelial cells after stimulation by inflammatory mediators (mediated by NF-κβ). Several polymorphisms in the SELE gene increase adhesion activity of E-selectin, dramatically increasing the risk of atherosclerosis and premature coronary artery disease.[49,50]

The primary therapeutic aim for carriers of a SELE polymorphism is to decrease NF-κβ stimulation, in turn reducing SELE expression. Maintaining high antioxidant potential has been shown to decrease NF-κβ activation.[51,52] Thus, higher levels of dietary antioxidants and possibly supplemental antioxidants may be beneficial. The proinflammatory cytokines tumor necrosis factor-α

and interleukin-1 also increase NF-κβ activation. Antioxidants, fish oil,[53] and milk thistle (silymarin) supplementation have each been shown to suppress interleukin-1 and tumor necrosis factor-α production directly and would therefore lower NF-κβ activation.

Electrolytes and Hypertension

Hypertension is an independent risk factor for coronary artery disease and for stroke. Therapeutic response to sodium restriction in hypertensive individuals is highly variable. A SNP in the angiotensinogen gene (AGT) allows an amino acid substitution in which threonine (T) replaces methionine (M) at amino acid 235. The T allele is associated with increased production of angiotensin, with a tendency for higher blood pressure. There is a stepwise increase of serum AGT from MM to MT to TT genotypes among persons with hypertension[54] and those with normal blood pressure.[55] Although there have been some discrepancies between studies, a meta-analysis of all studies published between 1992 and 1996 showed the 235T allele had a consistent, mild association with hypertension (OR = 1.20), a positive family history of hypertension (OR = 1.42), and more severe hypertension (OR = 1.34).[56]

The 235T allele of the AGT gene is associated with greater blood pressure decreases than the 235M allele after an intervention to reduce sodium intake (>5 mg/day).[57] Persons with the TT and MT genotypes showed significant systolic blood pressure reductions when consuming mineral salt compared with control subjects (P <0.02 and P <0.001, respectively), but persons with the MM genotype did not (P <0.10). The net adjusted systolic and diastolic blood pressure reduction was –8.6 mm Hg systolic/–3.9 mm Hg diastolic for persons with the TT genotype, –9.0/–5.2 mm Hg for those with the MT genotype, and –5.3/–1.0 mm Hg for the MM genotype.

Aerobic exercise was effective in reducing blood pressure but only in the MM (–3.7 mm Hg) and MT (–3.4 mm Hg) genotypes, and not in the TT (–0.4 mm Hg) individuals, among 477 previously sedentary white Americans.[58] Finally, the use of angiotensin-converting enzyme inhibitors produced more dramatic reductions in blood pressure in 235T allele carriers (TT and MT) than in the MM genotype,[59,60] illustrating the notion that diverse modifications in "environment" (diet, exercise, targeted pharmaceuticals) may produce similar alterations in phenotype (in this case, blood pressure) among genetically susceptible individuals.

Homocysteine and Micronutrients

As mentioned previously, one common physiologic effect of SNPs is a decreased binding affinity of a vitamin or mineral coenzyme for the structurally altered enzyme. There is mounting evidence that in most cases, the diminished rate of reaction of that polymorphic enzyme can increase with high-dose cofactor micronutrient supplementation.[61] Perhaps the best studied example of this model is the enzyme 5,10-methylenetetrahydrofolate reductase (MTHFR), which is responsible for re-methylating homocysteine into methionine, allowing methylation reactions to occur efficiently in the body. When methylation reactions are impaired, plasma homocysteine levels rise. Elevated homocysteine values have been associated with increased risk of atherosclerosis,[62] risk of early coronary artery disease,[63,64] increased risk of hemostasis and venous thrombosis,[65,66] decreased bone density,[67], neural tube defects, spina bifida,[68,69] and acute leukemia in adults.[70] The risk of heart disease increases for heterozygotes as well as 677T/T homozygotes.[71] Folic acid, vitamins B_2 (as flavin adenine dinucleotide [FAD]), B_6, and B_{12} are all cofactors in the methylation cycle, and a dietary deficiency of any of these vitamins can result in elevated homocysteine levels. However, elevated homocysteine levels can also result from two common polymorphisms in MTHFR: a 677C-T nucleotide substitution and a 1298A-C nucleotide substitution. Someone with a 677T/T genotype has a 50% reduction in MTHFR enzyme activity, whereas a 1298C/C genotype has a 32% reduction. In one study, approximately 28% of patients with elevated homocysteine did not respond to supplementation with folic acid, vitamin B_{12}, and vitamin B_6 because they had the 677T/T genotype and severely impaired MTHFR activity.[72] It is worth noting that the 677C-T polymorphism occurs in the FAD site of MTHFR, suggesting that vitamin B_2 supplementation may be a critical component.[73]

Three rational therapeutic strategies may help to resolve elevated homocysteine levels. First, high-dose supplementation of the vitamin cofactors of MTHFR, which relies on the simple logic of the law of mass action in chemical reaction: higher concentrations of substrates drive the chemical reaction forward. Second, the metabolic products of the MTHFR enzyme, namely 5-methyltetrahydrofolate, may be supplemented. Third, alternate re-methylation pathways may be stimulated, namely, by supplementing trimethylglycine or betaine as alternate methyl group donors. In practice, because of the low cost and high degree of safety associated with each of these options, all three strategies may be employed simultaneously. Regardless, serial plasma homocysteine measurements allow the practitioner to determine that the therapy employed has been successful.

Although the science of nutrigenomics is still in its infancy, several principles have become clear with enormous potential impact for clinical medicine. Nutrients act as dietary signals that alter gene expression (nutrigenomics). In individuals with specific polymorphisms, their specific genetic variation may render that individual more or less sensitive to specific nutrients or environmental stimuli and, therefore, may help determine optimal diet and lifestyle (nutrigenetics). Knowing the effects of these environmental stimuli on gene expression allows us to utilize this information proactively to alter gene expression and to mitigate risk for developing various forms of chronic disease, like cardiovascular disease. These principles of nutrigenomics and nutrigenetics hold true for macronutrient balance in the diet, as well as for micronutrients, such as vitamins, minerals, and electrolytes. Although our primary focus here has been on nutrient–gene interactions, the same principles hold true for lifestyle changes and targeted pharmaceuticals. Nutritional intervention is merely a more specific application of environmental modification to alter gene expression. What should be clear is that as our knowledge of gene–gene and gene–environment interactions increases, so too will our capacity for delivery of increasingly personalized and primary prevention.

GENOMIC TESTING

From Early Detection to Prevention

We use the term susceptibility gene to refer to a polymorphism that may render us more susceptible to development of a chronic disease when we are exposed to an adverse environment. Most susceptibility genes have a low positive predictive value (the probability that a disease will develop in a person with a positive test result) and a low attributable risk (the proportion of cases of a disease that can be attributed to a susceptibility gene).[74] Therefore, some researchers have questioned the clinical utility of susceptibility genetic testing,[75] but such arguments, by applying a single-gene/single-disease model to susceptibility genes, miss the potential

clinical relevance. Susceptibility genes, much like taking a family history, must be seen as important but incomplete contributors in what is invariably a multifactorial risk assessment. In terms of health outcomes, preventive genomic polymorphisms raise risk modestly and are additive in their effects (gene–gene interactions), and their actual phenotype expression is strongly affected by diet, lifestyle, and environment (gene–environment interactions). Rather than negate their clinical utility because of a low positive predictive value and a low attributable risk, these polymorphisms begin to offer a molecular basis for understanding the pathophysiology of complex multifactorial diseases, and an understanding of the environmental factors that affect gene expression begins to evoke effective therapeutic strategies.

Because environment is broadly understood to refer to anything outside the genome itself, therapeutic regimens may be constructed to include any portion of the environment that has been shown to affect gene expression and phenotype. This is truly a holistic approach because effective therapeutic strategies may involve diet, nutritional, and targeted pharmaceutical supplementation; lifestyle and behavioral modification; and avoidance or elimination of toxins, xenobiotics, and microbes. Intervention at any level of our "environment" may prove clinically beneficial.

Functional medicine is the clinical discipline designed to promote health, to anticipate and prevent disease, or to correct an existing disease by improving physiologic function. The underlying assumption is that health and disease lie on the same continuum, and the connecting thread of the continuum is physiologic function. Before the manifestation of any frank disease, a progressive loss of homeostasis and increasing dysfunction occur. Clinical intervention in this strategy may begin at the earliest signs of imbalance.[76] The promise of preventive genomics is that the point of effective intervention may begin even earlier, before the beginnings of physiologic dysfunction.

Clinical Challenges

Preventive and nutritional genomic testing in clinical practice has its critics, who predominantly argue that there are insufficient numbers of clinical trials to demonstrate the diagnostic and therapeutic efficacy of genomic profiles.[77] However, rather than demonstrating that all pregenomic testing is "premature and scientifically unsound," as suggested recently by Dr. Muin Khoury of the CDC,[78] such objections merely underscore the perspective shared here. Namely, it is precisely because chronic disease is multifactorial with complex gene–gene and gene–environment interactions that the diagnostic and therapeutic utility of preventive genomic testing must meet the four criteria of being relevant, prevalent, modifiable, and measurable. The last criterion, measurable, is critical at this early stage of preventive genomic testing. We must be able to measure beneficial phenotypic, physiologic changes in individuals that result from the therapeutic strategy employed. There will always remain a possibility that other genetic polymorphisms or other environmental influences that we have not yet identified may also affect an individual's disease risk.

A similar cautionary argument should be made in cases in which current genomic knowledge offers conflicting therapeutic advice. A man with an Apo-E4 allele presumably should not drink alcohol, but what if he also has a CETP Taq1B polymorphism for which alcohol has been shown to boost HDL cholesterol levels dramatically? At present, we do not know the answer to this clinical conundrum. Fortunately, because fractionated lipid levels are easily measurable, the effects of moderate, daily alcohol intake on such a specific individual's lipid profile may be easily ascertained. Thus, medicine must ultimately be empirical, relying on trial and error until the desired result (e.g., lower serum cholesterol) is achieved.

Bioethical Considerations: Opportunities and Potential for Discrimination

Genetic information, because it represents an unchangeable state, has the potential at least in theory to be used in a manner by insurers, employers, and society at large. However, it should be noted that the paradigm for such discrimination views genetic information as representing an individual's immutable limitations, as typified by single-gene diseases (e.g., Tay-Sachs disease, Huntington's disease, sickle cell anemia).

A fundamental cornerstone of preventive genomics is the idea that the phenotypic outcome of any unique genotype is modifiable through environmental change. Preventive genomic testing, rather than revealing an individual's genetic limitations, more accurately reflects an individual's genetic potential, given the right environment. Genetic polymorphisms have the potential to guide an individual to adopt appropriate dietary, lifestyle, and environmental changes that can optimize health and longevity.

Now that we know there are irrefutable connections between genes and environment, and we are learning their myriad effects on health and disease, ignorance is no longer ethically neutral. Choosing not to use genomic information in treating patients, now that its health implications are being effectively documented, is ethically untenable. For the first time in the history of medicine, preventive genomic testing allows us to assess individual risk for development of chronic diseases, to develop comprehensive risk reduction strategies before imbalances in homeostasis occur, and to institute optimal therapy interventions for patients who are already sick. This new personalized medicine, made possible by the advent of preventive genomics and nutrigenomics, offers practitioners and patients new opportunities for the prevention and treatment of disease and for the promotion of optimal health.

SUMMARY

Preventive genomic testing exploring both nutrigenomics and nutrigenetics is both new and exciting. It affords practitioners both novel and effective avenues to develop personalized therapeutic regimens and to promote optimal disease prevention strategies. Although what we know is dwarfed by what we do not know, this imbalance does not negate the current therapeutic power that the last 20 years of genomic research has revealed. We agree with the following assertions made recently by Loktionov[79]:

- There are many examples of effective research on gene–environmental interactions.
- There is sufficient evidence to make clinical recommendations on the basis of individualized genomic predisposition.
- There is a need for research on traits that protect from, as well as predispose to, disease.
- Environment modification, especially dietary changes, may be the easiest and most efficient way to influence the risks of many diseases common today.

It is little wonder that Paul Berg, the pioneering researcher in recombinant DNA and genetic engineering and the winner of the Nobel Prize for Chemistry in 1980, once quipped, "All disease is genetic even when it is also something else." However, it is equally true to say that all disease is environmental even when it is also genetic. The symphony between nature and nurture is the very essence of life and health for all creatures who call this Earth their home.

Discussion, *152*

INTRODUCTION

Despite many research studies since the original publication of this chapter in 1985, there has been little change in the diagnostic value of hair analysis (HA). Outside its accepted use for diagnosis of heavy metal toxicity, at this time, HA still has only limited clinical application.

In recent years, several attempts have been made to standardize HA testing techniques,[1] but laboratories still do not have an agreement on procedures for handling a hair sample.[2-4]

Many conditions and diseases have been tested for abnormal HA patterns, and a number have been shown to have patterns differing significantly from the norm, including the following:

- Learning disabilities[5-7]
- Birth defects[8,9]
- Hyperactivity[10-12]
- Down syndrome[13,14]
- Neurosis and psychosis[15]
- Senile dementia[16]
- Autism[17]
- Alopecia areata[18]
- Insulin-dependent diabetes mellitus[19,20]
- Cystic fibrosis[21]
- β-Thalassemia[22]
- Spasticity in children[23]
- Repeated exposure to radiographs[24-26]
- Nasopharyngeal cancer[27,28]
- Aplastic anemia[29]
- Metabolic syndrome[30]
- Breast cancer[31]
- Bone mineral density[32]
- Type 2 diabetes[33]

HA has been used successfully to test for drug abuse,[34-41] and studies have been performed in several locations examining the validity of using HA to test drug use before the reinstatement of driving licenses.[42,43] However, drug metabolites are not found on most commercial HAs.

HA appears to offer potential as a correlating diagnostic tool in a few of the listed conditions, although hair mineral patterns should not be used exclusively for diagnosis. For example, the high hair sodium values in infants with cystic fibrosis show very little overlap with those in controls, and one study demonstrated that children with learning disabilities can be diagnosed with 98% accuracy because of a consistent pattern of high hair values of cadmium, manganese, and chromium in conjunction with low values of lithium and cobalt.[5] The usefulness of HA as a research tool can hardly be questioned. However, significant controversy exists about using the method for the clinical diagnosis of diseases other than heavy metal toxicity and as an indicator of nutritional status. Moreover, multiple studies question the inter- and intra-laboratory accuracy of HA.[44-48] The difference between research and clinical use is significant. Although it may be of interest in a research setting in which patients with various skin conditions have lower mean levels of hair magnesium than controls, the two groups overlap so much that the procedure is diagnostically useless.[18] Moreover, even when an altered HA pattern was associated with a

disease, generally there have been few investigations as to whether mineral supplementation would affect the clinical condition or even revert the hair mineral pattern to normal.

Wide overlap of values in disease and control groups is frequently the case with HA, resulting in excessive false-positives and false-negative results. For example, mentally retarded patients have been found to have lead, sodium, and potassium hair values approximately twice those of controls,[13] but the standard deviations are extremely large for some minerals (for sodium, 1644.71 ± 1814.93 versus 744.43 ± 1987.00[18]; and for potassium, 870.15 ± 1009.19 versus 408.35 ± 689.99), and the large overlap greatly reduces the clinical use of HA. In addition, many of the altered HA patterns associated with the diseases previously listed are as yet unconfirmed.

SPECIFIC MINERALS

Calcium and Magnesium

Hair calcium and magnesium values were found to be elevated in patients with fibromyalgia.[49] High hair calcium content has been associated with a reduced risk of coronary heart disease.[50] Low hair calcium content has been found in the last trimester of pregnancy,[51] but hair calcium content increased in response to supplementation during pregnancy.[52] Low hair magnesium levels have been reported in autistic children, children with attention deficit hyperactivity disorder, patients with various skin disorders, and patients with several types of leukemia, whereas high levels have been reported in conjunction with dyslexia and Prader-Willi syndrome.[12,17,18,53-55] The meaning of these associations remains unknown for the most part.

A 2001 study concluded that analysis of hair calcium and phosphorus content was of value as a complementary detection tool in abnormalities of bone metabolism.[56] Elevations in both calcium and magnesium were correlated with a low dietary calcium/magnesium ratio in one study, suggesting that this finding may be indicative of an induced hyperparathyroidism,[57] but that hypothesis remains unproven. Hair calcium and magnesium also vary in response to the hardness and pH of the water in which the hair is usually washed.[50] Supplementation of dietary magnesium has been reported to increase hair magnesium levels in deficient children.[58] Nonetheless, in one study of congenital hypomagnesemia, researchers concluded that hair magnesium level was not a useful tool in monitoring mineral status because the values were higher in affected subjects than in subjects who were not deficient.[59]

There is limited evidence to support the use of hair calcium and magnesium measurements in clinical diagnosis at this time.

Chromium

Hair chromium content is low in insulin-dependent diabetics,[20] although there is much overlap with normal persons. Chromium levels decrease with age,[22] but the meaning of this change remains unknown. Hair and tissue chromium levels vary greatly during pregnancy, being very high during the first few months of normal pregnancy and subsequently decreasing.[60,61] Late in pregnancy, hair chromium content typically becomes low,[62] suggesting deficiency.[34] However, high hair chromium value in pregnancy is associated with low birth weight infants.[63] In patients with gestational diabetes, hair chromium content is high early in pregnancy but decreases in late pregnancy.[61] Increasing dietary intake of chromium has been linked to increasing hair chromium values,[64] but supplemental chromium does not seem to alter hair levels.[60,65]

Although normal and deficiency ranges should be more clearly defined, hair chromium content appears to have potential future use in clinical settings. However, current knowledge remains inadequate to help clinicians treat patients on the basis of abnormal hair chromium levels.

Copper

Oral contraceptive use is associated with decreased hair copper and increased serum copper.[66] High hair copper levels are associated with being female, lactation, idiopathic scoliosis, and pregnancy in some, but not all, studies.[67-70] Surprisingly, conditions that affect systemic copper status have been shown not to affect hair levels. Copper deficiency,[71] Wilson's disease,[72,73] and cirrhosis[74] do not significantly alter hair copper content. Hair copper levels also vary with geographic location.[75] However, fur and liver copper values have been found to correlate in rats,[74] and one study reported that supplemental copper raises hair copper levels.[76] Hair color also has been found to influence the levels of copper in the hair.[70,77]

At this time, hair copper measurement appears unreliable for clinical application.[67]

Manganese

Levels of hair manganese in mothers of infants with congenital malformations and their offspring were significantly lower in one study,[8] which may allow maternal hair manganese levels to be used as an indicator of the risk for malformations. Both nonsignificantly altered[78] and normal levels of manganese[79] have been reported in patients with epilepsy.[78] Hair manganese values have been reported to be elevated in people with violent behavior, with varying levels of significance.[79,80] Evidence that manganese supplementation affects behavior does not appear to exist at present.

Hair manganese may serve as a useful research tool in the study of altered behavior, but the most promising value of hair manganese may lie in the prediction of congenital malformations.

Selenium

Levels of selenium in well water and hair show good correlation.[81] High hair selenium levels are seen in toxicity,[82,83] and low levels are seen in deficiency.[84] Low hair selenium values have been reported in babies with neural tube defects and their mothers,[9] as well as in patients with phenylketonuria.[85] Tissue selenium values reflect short-term variations in intake,[40] and hair levels of the element rise significantly after supplementation. [86-88]

As with chromium, insufficient data are now available to establish reliable norms for measurement of hair selenium values, and the incidence of false-positive and false-negative results remains unknown. Hair selenium measurement shows promise for clinical use when these problems are resolved.

Sodium and Potassium

It is generally accepted, even by proponents of HA, that hair sodium and potassium do not reflect dietary status. High elevations of hair sodium may be diagnostic in cystic fibrosis,[21] but require confirmation. A relatively low sodium/potassium ratio has been reported in celiac disease.[88] Although many HA advocates cite low hair sodium and potassium as indicative of "adrenal exhaustion," the only (preliminary) study exploring this subject reported that hair sodium and potassium did not correlate with

adrenal function.[89] Except for cystic fibrosis, hair sodium and potassium appear to hold little promise for clinical use.

Zinc

Hair zinc levels have received more research attention than any other mineral. Low hair zinc has been associated with zinc deficiency, anorexia nervosa, hyperactivity, gender, age, atherosclerosis, β-thalassemia, vegetarianism, lung cancer, leukemia, celiac disease, epilepsy in males, epilepsy in general, short stature in childhood, poverty, insulin-dependent diabetes mellitus, neural tube defects, and during pregnancy.* It also has been reported in neonates if the time between pregnancies is short.[108]

Because a few of these conditions have been associated with potential zinc deficiencies and supplemental zinc has been shown to increase hair zinc levels, practitioners who use HA often rely on hair zinc as an indicator of zinc status. However, one trial reported that hair zinc levels declined after supplementation.†

Other factors that affect hair zinc levels also interfere with the clinical use of this tool. Shampooing and dying affect hair zinc levels,[111] as does the sex of the subject,[111-115] age,[70] and hair growth rate. Malnourished children have shown both low[105,116,117] and high[118] hair zinc.

Poor correlations between hair zinc and height,[119] weight, and zinc consumption also have been reported,[76,112] although one study reported a correlation among hair zinc, weight, and zinc consumption.[119] Another study found that obese people of both sexes had higher hair zinc than those of normal weight and that there was a correlation between the degree of obesity and higher hair zinc levels.[120]

Although low hair zinc levels have been reported in patients with insulin-dependent diabetes mellitus,[109] generally there is considerable overlap between cases and controls. To further complicate the picture, in a study of female children of non–insulin-dependent diabetes mellitus parents, hair zinc was found to be significantly higher compared with women with no family history of non–insulin-dependent diabetes mellitus.[121]

At this time there is no definitive understanding of the meaning of abnormal hair zinc levels. The hypothesis that high hair zinc levels reflect acute deficiency, whereas low levels indicate chronic deficiency remains unproved.

Other Minerals

Hair iron was found to correlate positively with serum ferritin,[122] although the clinical relevance of this finding is unclear.[123] Hair lithium has been reported to show a linear response to extra-dietary sources.[7] Low hair levels of lithium have also been reported in conjunction with heart disease, learning disability, and violent behavior.[7] However, research findings are far from the point at which hair lithium could be used to help clinicians diagnose or treat these conditions.

DRUG ABUSE

HA has been used to detect drugs of abuse and their metabolites when urine tests were negative.[34,36] HA has been used as evidence in a court of law concerning past drug abuse.[35] Although there are concerns about the role of HA in testing for drug abuse,[124] HA does seem to be a valuable tool in drug screening.[37,38,49,50] As mentioned, drug metabolites, not mineral levels, are measured in these trials, and drug metabolites typically are not reported on most commercially available HAs.

RATIOS

The experimental documentation for most of the "ideal" ratios that have been published by several HA companies has not been found. The zinc/copper ratio has been reported to be altered in violent patients.[80] This ratio was also elevated in survivors of myocardial infarctions.[125] Strong correlations between several mineral ratios and atherosclerosis have also been reported[126]; however, the clinical significance of these ratios is not known. The magnesium/zinc ratios helped to separate healthy (less than 1:1) from epileptic (more than 1:1) subjects in one study.[99]

DISCUSSION

Hair mineral analysis is conceptually enticing and potentially a valuable clinical tool. However, problems abound with standardization of sampling, handling, and analysis of hair samples.[44,45] Additionally, reference values can differ widely,[127,128] and many variables affect the results (see Austin for a review)[129]:

- Gender[77]
- Age[77,130,131]
- Environment[132-134]
- Hair color[70,77]
- Cold waving
- Bleaching
- Exogenous contamination[50]
- Variations in mineral content within a given sample

This is further aggravated by the reporting of different results on the same sample from different laboratories.[45,48,135] The distribution of elements within the lipid and nonlipid portions of hair and the treatment of the sample before testing may explain these variances.[4,136] As noted, dietary intakes do not consistently correlate with hair levels, and hair color, sex, age, and other variables appear to significantly affect levels of some minerals. Separate norms for age, gender, and hair color are now being established.[70,131,137] However, reviews of the literature attempting to establish reference values continue to show a large variance in mean values, standard deviations, and ranges.[75,138] Additionally, there is no basis for the nutritional advice suggested by some laboratories.

As a result of the gulf between available information on the one hand, and the clinical interest by some practitioners on the other, several articles have appeared decrying the misuses of HA.[44,45,139-141] Hambidge[140] said, "There is a wide gulf between the limited and mainly tentative justification for their use on an individual basis and the current exploitation of multi-element chemical analysis of human hair."

Klevay and associates[142] acknowledge the experimental usefulness of HA but go on to say that, "its use in clinical medicine for diagnosis, prognosis, and therapy will remain limited until validation by the standard methods of clinical investigation is achieved." Steindel and Howanitz[141] concluded:

> *Physicians and other health care professionals who are considering ordering hair analysis to assess nutritional status or who are basing nutritional counseling or therapy on hair analysis should reconsider this approach unless and until the reliability of hair analysis value is established and evidence becomes available that clinical recommendations based on hair analysis improve patient outcomes.*

†References 52, 90, 91, 102, 109, 110.

Widespread use of speculative diagnostic procedures invites condemnation, especially when the burden of these speculations falls on the pocketbook and psyche of the patient. HA is a valid and useful screening tool for toxic metal exposure (lead, mercury, cadmium, arsenic, and selenium). It has the potential of becoming a clinical tool of considerable use in other areas. Current abuse and nonstandardization of laboratory procedures are more likely to hinder this development than to help it.

Conclusion, *159*

INTRODUCTION

Proper digestion is a prerequisite for optimum health, and incomplete or disordered digestion can be a major contributor in the development of many diseases. The problem is not only that ingestion of the best nutritional substances may be of little benefit when breakdown and assimilation are inadequate, but also that incompletely digested macromolecules can be inappropriately absorbed into the systemic circulation. This process can lead to various immune complex deposition diseases and is now theorized to be an integral part of the etiology of food allergies.

Adequate gastric hydrogen chloride (HCl) is also necessary for protection of the gastrointestinal tract from ingested pathogens and for the maintenance of proper bowel flora. A healthy flora is known to be important for proper immune function, vitamin absorption, and the prevention of opportunistic infections such as *Candida albicans* in the gut.

The Heidelberg gastric analysis technique was developed to measure the hydrogen ion concentration (pH) of the digestive tract and determine the acid secretory ability of the parietal cells. Its use of radiotelemetry allows the gathering of this important information in a convenient and accurate manner.

The Heidelberg pH capsule system had its origin about 50 years ago at Heidelberg University in Germany. In research sponsored by Telefunken, a West German electronics firm, the inventor H.G. Noeller studied gastric acidity in 10,000 people. Since then, about 140 studies, according to a PubMed inquiry, have used the Heidelberg system to investigate various aspects of digestion.[1-7] Physicians and researchers now use this technique for measuring the pH of the digestive system.

PHYSIOLOGY OF DIGESTION IN THE STOMACH

The epithelium of the stomach contains many gastric glands. These tubular glands consist of parietal, chief, and mucous cells. The antral portion of the stomach produces the digestive hormone gastrin, the release of which is stimulated by the following:

- Vagal nerve stimulation
- The physical bulk of the ingested food distending the stomach
- Partially digested proteins

After gastrin is absorbed into the bloodstream, it is carried to the gastric glands, where it stimulates the parietal cells to produce HCl acid and, to a lesser extent, the chief cells to produce digestive enzymes (such as pepsin and intrinsic factor). With adequate stimulation, the parietal cells increase their production of HCl by as much as eightfold.

When the pH of the stomach reaches about 2, the gastrin mechanism becomes blocked and feedback causes the parietal cells to decrease production of HCl. This concentration of hydrogen ions (by a factor of 100,000) is an energy-dependent process.

Dietary protein is composed of amino acids held together by peptide linkages. Pepsin A, the major gastric protease, cleaves these in the stomach and is most active at pH values of between 2 and 3. It is inactive at a pH of 5 and above. Consequently, to have any significant digestive effect in the stomach, the gastric juices must be acidic.

Trypsin (a protein-splitting enzyme secreted by the pancreas) completes the process, yielding amino acids and dipeptides. The biochemical messenger that

stimulates this pancreatic secretion is the acidic bolus of food moving from the stomach into the duodenum.

PROCEDURE

Equipment

The Heidelberg system consists of the following equipment:

- Radiotelemetry capsule—a hard plastic capsule (about 2 cm long × 0.8 cm in diameter) that contains a miniature radio transmitter, a pH sensing device, and a saline-activated battery.
- Waistband antenna—receives the signal from the capsule and relays it to the receiver.
- Receiver/recorder—receives and translates the signal. The pH reading is displayed on a meter and recorded by a continuous printer for a permanent record. The receiver also contains a calibration probe used to calibrate each capsule with known pH 1 and 7 solutions.
- Heater block—maintains the calibrating solutions at 37° C.

Methods

The test can be conducted in two ways: the tethered capsule repeat challenge and the flow-through method. Each gives different information and has its advantages and disadvantages. For both procedures, the test begins after the patient has fasted (food and liquid) for 8 hours.

The Tethered Capsule Repeat Challenge

In this procedure, the capsule is tethered so that it remains in the stomach while the stomach is challenged by the ingestion of a saturated sodium bicarbonate solution (i.e., baking soda).[8] The challenge solution triggers a rise in stomach pH and a subsequent attempt by the parietal cells to reestablish appropriate acidity. The majority of people have a normal initial pH of between 1 and 2.3. Abnormalities of stomach secretions are usually found only after the stomach is challenged. (A more involved protocol can be found in Wright.[8])

The procedure is as follows:

1. The waistband antenna is fastened around the patient's waist and the receiver/recorder is turned on and calibrated.
2. The patient swallows the capsule, which is attached to a 1-meter long, thin cotton thread (a small amount of distilled water is allowed). The pH reading typically starts at 7 and falls toward 1. After about 5 minutes, the capsule reaches the bottom of the stomach (which normally displays a pH of between 1 and 2) and the remaining thread is taped to the cheek to prevent movement of the capsule out of the stomach and into the intestine.
3. If the fasting pH is normal, the patient swallows the first challenge of 5 mL of the alkaline solution. Within 30 seconds, the pH normally rises to 7 and the patient is asked to lie down on his or her left side (to keep the stomach contents in as long as possible).
4. If stomach function is normal and acid is secreted sufficiently in response to the alkali challenge, the pH returns to normal (between 1 and 2) within 20 minutes.
5. The challenge is repeated up to four times, as long as the response time is within 20 minutes.

Flow-Through Capsule

In this procedure, the capsule is not tethered to a thread and is allowed to move freely from the stomach into the duodenum and the rest of the small intestine. The proponents of this method claim that this allows measurement of the gastric emptying time and intestinal pH, both of which are important parameters.

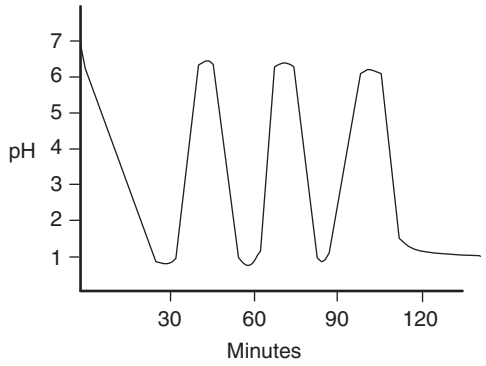

FIGURE 18-1 Normal Heidelberg gastrogram.

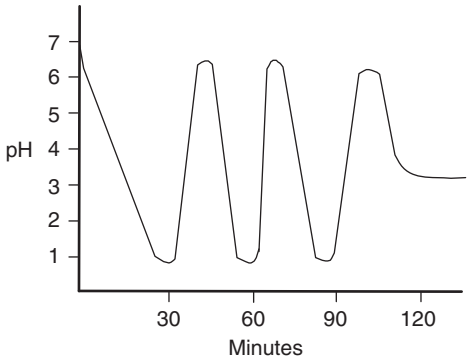

FIGURE 18-2 Hypochlorhydric gastrogram.

INTERPRETATION

Results may be classified as normal, hypochlorhydria, achlorhydria, and hyperchlorhydria.

Normal. The patient successfully reacidifies after four challenges (Figure 18-1). Curve number 1 shows the capsule entering the digestive tract; number 2 shows the capsule reaching the bottom of the stomach and alkaline challenge occurring; and number 3 shows a pH rise after swallow and subsequent reacidification within 20 minutes.

Hypochlorhydria. The patient requires more than 20 minutes to reacidify (Figure 18-2). Curve number 1 shows a pH of 1 being reached after 30 minutes. Note that on the third challenge, the pH comes back only to about 4.

Achlorhydria. The patient's stomach shows little acid secretion and is not able to secrete enough acid to bring the pH below 4, even on the first challenge (Figure 18-3). The pH remains at about 4.2 for almost 2 hours.

Hyperchlorhydria. The gastrogram shows extremely rapid reacidification (within 5 minutes) after each challenge.

Depending on specific curve components, some investigators believe that mucous quantity, fresh or chronic ulcers, and acute gastritis conditions can sometimes be identified.

CLINICAL APPLICATION

Although much is said about hyperacidity conditions, probably more significant health problems are caused by hypochlorhydria and achlorhydria. Direct measurement of gastric acid secretion

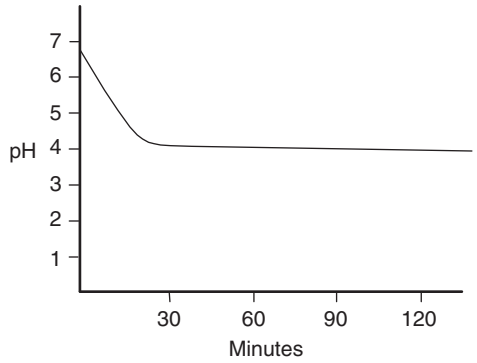

FIGURE 18-3 Achlorhydric gastrogram.

BOX 18-1 Common Symptoms of Low Gastric Acidity

- Bloating, belching, burning, and flatulence immediately after meals
- A sense of "fullness" after eating
- Indigestion, diarrhea, or constipation
- Multiple food allergies
- Nausea after taking supplements
- Itching around the rectum

Modified from Wright JV. Healing with nutrition. Emmaus, PA: Rodale Press, 1985.

through intubation and aspiration is uncomfortable and unacceptable to many patients. The Heidelberg pH capsule system offers a convenient and accurate outpatient testing system to clinicians interested in evaluating gastric function.

HCl, pepsin, and intrinsic factor are involved directly in digestion and contribute to the chemical changes in the intestines that assist in the absorption of many nutritional factors. For example, vitamin B_{12} absorption requires intrinsic factor, whereas zinc, calcium, and iron are poorly assimilated when gastric acidity is low.[9-11]

INDICATIONS

Many symptoms and signs suggest impaired acid secretory ability, and a number of specific diseases have been found to be associated with achlorhydria and hypochlorhydria (particularly human leukocyte antigen-B_8–related autoimmune diseases). These are listed in Boxes 18-1, 18-2, and 18-3.[12-23] It appears that the presence of *Helicobacter pylori* is a major factor in both achlorhydria and hypochlorhydria.[24,25]

Aging

Numerous studies have shown that acid secretory ability decreases with age. Low stomach acidity has been found in more than half of those older than age 60.[26,27] One study of the elderly found that their tissue nutrient levels could be saturated only through use of intramuscular supplementation; oral supplementation was ineffective. The authors speculated that this was due to atrophy of various digestive organs.[28]

BOX 18-2 Common Signs of Low Gastric Acidity

- Weak, peeling, and cracked fingernails
- Dilated capillaries in the cheeks and nose (in nonalcoholics)
- Postadolescent acne
- Iron deficiency
- Chronic intestinal parasites or abnormal flora
- Undigested food in stool
- Chronic candidal infections
- Upper digestive tract gassiness

Modified from Wright JV. Healing with nutrition. Emmaus, PA: Rodale Press, 1985.

BOX 18-3 Diseases Associated with Low Gastric Acidity

1. Addison disease
2. Asthma
3. Celiac disease
4. *Dermatitis herpetiformis*
5. Diabetes mellitus
6. Eczema
7. Gallbladder disease
8. Grave's disease
9. Chronic autoimmune disorders
10. Hepatitis
11. Human immunodeficiency virus/acquired immunodeficiency syndrome
12. Chronic hives
13. *Helicobacter pylori* infection
14. Lupus erythematosus
15. Myasthenia gravis
16. Osteoporosis
17. Pernicious anemia
18. Psoriasis
19. Rheumatoid arthritis
20. Rosacea
21. Sjögren's syndrome
22. Thyrotoxicosis
23. Hyperthyroidism and hypothyroidism
24. Vitiligo

Data from references 13-24.

CONCLUSION

The Heidelberg pH capsule system is an effective and convenient method to determine gastric acid secretory ability under conditions simulating ingestion of food. Results are extremely valuable in identifying the large number of people who have impaired secretion function. Ramifications of impaired acid secretion are widespread. This technology has become an accepted method of assessing gastric pH in several research settings.

ASSESSMENT OF THE IMMUNE SYSTEM

Background

Immune physiology involves complex interactions between cells and proteins to mediate an effective response to infectious disease. A healthy immune system eliminates pathogenic microbes while simultaneously creating a biodynamic relationship with normal microflora. Because the immune system must also effectively distinguish between dangerous foreign invaders and self-antigens, immune dysfunction can result in autoimmunity, cancer, allergies, and asthma, in addition to infection. Healthy immune function is affected by age, gender, sleep, nutrition, and exercise. Natural therapies such as herbs, meditation, hydrotherapy, and supplements can also enhance and manipulate immune reactions.

A variety of tests can be used to evaluate the immune system. To determine what type of immune assessment to use for each clinical diagnosis, it is important to understand how underlying immune physiology contributes to a clinical picture. Clinicians can assess qualitative or functional activity of immune cells. Qualitative data may include things like types, number, and activation states of cells. Cells of the immune system express different proteins on their surface. These proteins, called biomarkers, allow us to identify different cells as well as their activation state. To assess immunodeficiency and lymphoproliferative diseases, the number of T cells and B cells must be quantified. Functional activity of immune cells involves putting the cells into an in vitro assay system, adding antigen or mitogen, and measuring a function such as cytotoxicity, cytokine production, or antibody secretion. Levels of proteins that are produced by lymphocytes and monocytes, such as cytokines and antibodies, can be analyzed as well. Tests of genetic predisposition to disease can be evaluated with genetic tests. An overview of the assays used to measure cells is found in Table 19-1. A description of these tests is found in Box 19-1.

MEASUREMENT OF ANTIBODIES

Antibody (also called immunoglobulin) is a protein made by B cells in response to antigen. Each B cell has specificity for one antigen. This specificity is determined by gene rearrangement long before a B cell ever encounters antigen. The antibody is found both on the surface of B cells and is secreted. B cells are primarily found in the lymph nodes, Peyer's patches of the gut, and spleen (80%); however, antibody is readily detectable in the blood and other bodily fluids.

Antibodies look like the letter "Y". Each part of the antibody has a different function: the arms bind specifically to antigen, whereas the base (the Fc region) allows the antibody to bind to receptors. This base region is called the "isotype." Antibodies come in multiple isotypes based on the constant region of their heavy chain. These different isotypes have functional importance. Some isotypes are better than others at triggering the complement cascade. The Fc receptors of other isotypes allow them to activate specific cells, such as mast cells and eosinophils.

Antibodies are essential to measuring immune function because they can act both as an indicator of disease and as a tool to measure the levels of other proteins and cells. Monoclonal antibodies are a powerful tool (see Box 19-2).

Measuring serum antibody is essential in patients who have repeated or severe infections. Low antibody levels in these patients may indicate that they have an immunodeficiency. Patients with myelomas and lymphoproliferative disorders may

have high antibody levels. For example, patients with alcoholic liver disease often have a polyclonal expansion of immunoglobulin-A (IgA), whereas patients with systemic lupus erythematosus (SLE) and Sjögren's syndrome have polyclonal IgG expansion.[1]

The type of isotype made by B cells can provide clues as to immunologic status of the patient (see Table 19-2).

The route and duration of exposure, type of antigen, and genetic background may all affect the isotype of antibody that is produced, as well as the subclass of antibody produced. Upon immediate exposure to a novel infectious organism, the body produces IgM. After the B cell makes IgM, it class switches to another isotype, as determined by a combination of activation proteins and cytokines. If the patient has been exposed to an infectious agent, the antibody usually will class switch to IgG.

TABLE 19-1 **Overview of Assays to Measure Specific Immunity**

TYPE OF IMMUNITY	ASSAYS
Humoral immunity	Antibody production: ELISA, cytometric bead array
Cellular immunity	Cytokines: ELISA, ELISPOT, cytometric bead array, RIA, intracellular cytokine staining
	Cytotoxicity: 51 chromium release assay
	Proliferation: CFSE, lymphocyte proliferation assay
Genetics	SNPs genetic microarray

CFSE, carboxyfluorescein succinimidyl ester; ELISA, enzyme-linked immunosorbent assay; ELISPOT, enzyme-linked immunosorbent spot; RIA, radioimmunoassay; SNP, single nucleotide polymorphisms.

IgG is the major antibody found in blood, and it consists of four subclasses, originally described in the 1980s according to their abundance in serum. IgG1 and IgG2 are present in much higher concentrations than IgG3 and IgG4. All subclasses of IgG are low in pediatric populations. Deficiency in some IgG subclasses results in increased susceptibility to bacterial infections.[2] IgG subtypes vary in their ability to activate complement and Fc receptor binding. IgG3 has a strong affinity for Fc receptors and has the greatest ability to activate complement. The type of antigen can influence the subclass of antibody response. For example, IgG2 antibodies appear to influence polysaccharide antigens, whereas protein antigens and whole bacteria preferentially elicit IgG1.[3-5]

IgG4 antibodies, found at lowest concentration in the serum, are generated to repeatedly presented antigens. IgG4 deficient individuals may be more susceptible to pyogenic infections of the respiratory tract. Antibodies against dietary antigens are frequently IgG4. In a community survey of 40 individuals, anti-food antibodies to milk, egg, and fish of the IgG4 subclass were found in a significant proportion of a healthy population, indicating that IgG4 antibodies against food antigens cannot serve as markers of atopic disease. Because IgG4 cannot activate complement, it has been hypothesized that it may serve for protective clearance mechanisms and may be a desirable response to dietary antigens.[6] IgG1 and IgG2 have also been found for dietary antigens, but the immunologic outcome of these subclasses may be food intolerance that is not caused by IgE mediated hypersensitivity.[7] A larger discussion of the immune response to food can be found in Chapter 15.

Antibodies of each of the IgG subclasses can be detected by a variety of techniques, including radioactive iodine labeling, antigen

BOX 19-1 **Testing Methods**

ELISA

Enzyme-linked immunosorbent assay (ELISA) is an assay used to measure proteins of the immune system. In ELISA, an antigen is fixed to the surface of a 96-well plate, then a specific antibody is incubated with the antigen so that it forms an immunocomplex. This antibody is linked to an enzyme that allows the antigen to be converted into a detectable signal, most often a change in color. The more antigen that is present, the darker the color.

ELISPOT

A variation of the ELISA is the enzyme-linked immunosorbent assay (ELISPOT). Peripheral blood mononuclear cells (PBMCs) are plated on a filter-bottom 96-well plate coated with anticytokine antibody. The plate is cultured 24 to 48 hours to allow cytokine secretion and capture on the plate. Cells are washed off and detector antibody is added, followed by enzyme substrate. Cytokine-secreting cells are identified as spots of secreted cytokine.

Cytometric Bead Array

A cytometric bead array uses multiplexed beads labeled with capture antibodies for specific analytes, such as cytokines or other serum proteins. Serum is added together with Phycoerythrin (PE) PE-labeled detector antibody. The antibody–antigen complex is run through the flow cytometer, and software calculates the level of each analyte based on PE fluorescence of each bead population relative to a standard curve.

Intracelluar Cytokine Staining

This technique uses the flow cytometer to ensure production of cytokines in short-term stimulated whole blood or PBMCs before the cytokines are secreted from the cells. One advantage of this assay is that multiple cell surface and intracellular markers can be analyzed in combination using multiparameter flow cytometry.

Chromium-51 Release Assay

To test the ability of CD8 T cells or natural killers (NKs) to kill, target cells are incubated with radioactive isotope of chromium-51, which can be released when the cell dies. The CD8 T cells or NKs are then placed in serial dilution with the antigen presenting cells. Antigen is added in the case of the CD8 T cells. When the target cells are killed by the CD8s, the amount of radioactivity or enzyme can be analyzed.

Lymphocyte Proliferation Assay

Proliferation capability of T cells can be measured by isolating PBMCs, separating the T cells, and incubating with tritiated thymidine (^{3}H). A mitogen such as lipopolysaccharide is added to the cell culture. This mitogen may induce cell proliferation. As the cells divide, they incorporate the ^{3}H into the DNA, and analysis of radioactivity can determine how many cell divisions occurred. An ELISA may also be performed to measure cytokine production by the CD4 T cell.

Carboxyfluorescein succinimidyl ester

Carboxyfluorescein succinimidyl ester (CFSE) can be used to measure cell division. In this assay, the parent cell is incubated with CFSE, which is incorporated into DNA during cell division. As the cell divides, each of the daughter cells contains half of the CFSE stain. Every subsequent cell division halves the amount of CFSE in the daughter cells. When these cells are run through a flow cytometer, a characteristic pattern is seen (see Figure 19-2).

coated red cells, immunofluorescence with antigen coated sepharose, radioimmunoassay (RIA), and enzyme-linked immunosorbent assay (ELISA) with monoclonal antibodies (Figure 19-1).[8]

IgA can also be made to infectious agents and occurs in two forms, IgA1 and IgA2. IgA in serum predominantly exists in the monomeric form, IgA1. The ratio of IgA1:IgA2 in serum is about 9:1. IgA found in secretions, termed secretory IgA, occurs as dimers. The ratio of IgA1:IgA2 in secretions varies, but is approximately 6:4 in saliva.[9] Because IgA is found at mucosal surfaces and lines the mucosal surface of the gut, it is not uncommon to find IgA antibody specific for food antigens. Because IgA is at high levels in secretions, it can be found in saliva in addition to serum, and salivary IgA tests are readily available.[10,11]

An immune response to parasites, specifically worms, triggers an IgE response.[12] IgE elicits an immune response by binding to Fc receptors on mast cells, eosinophils, and basophils, causing degranulation and cytokine release. In atopic individuals, IgE is also made to allergens. IgE is at low levels in the blood. Measurement of total serum IgE is useful in patients in whom parasitic infection is suspected, but is not valuable for measuring allergies. Thus, the most common method for allergy testing is the skin prick test.[13] In this test, a small amount of the suspected allergen is placed on the skin. Then the skin is pricked so that the allergen goes under the skin's surface. If the patient is allergic to the allergen, swelling and redness will appear within 15 to 20 minutes.

Measuring total antibody in blood involves protein electrophoresis or ELISA, and is valuable. However, quantifying the total amount of antibody specific for an antigen is even more desirable. Antibody titers for common antigens, such as those found in vaccines, can be ordered. Each laboratory has its own reference levels for titers, because the sensitivity of the test is related to the specificity and affinity of the reagents they are using.

Specific antibodies, rather than total levels, are also measured for circulating autoantibodies. These antibodies can be detected with immunofluorescence, RIA, and ELISA.[14] Immunofluorescence involves examining the tissue directly with microscopy and is the least sensitive of these tests. The patient's tissue is frozen and sections cut on a cryostat. This tissue is incubated with patient serum, such that autoantibodies in the serum can bind. A fluorescently tagged secondary antibody specific for human immunoglobulin is then used to detect the autoantibodies. Immunofluorescence examination of biopsy specimens of damaged or normal tissue may reveal deposits of immunoglobulins caused by antibodies reacting with an organ or tissue specific antigens. This approach is especially important in the diagnosis of antiglomerular basement antibody disease and bullous skin disorders, but may show false positives when used for SLE. (See Table 19-3 for a listing of common autoantibodies.)

RIA is a far more sensitive test used for measuring antibodies that are in low concentrations. In RIA, an antibody specific for human antibody is tagged with a radioactive isotope. When this antibody is incubated with an autoantibody, the contact detects even low levels of autoantibody. ELISA is very similar to RIA; however, the enzymatic substrate is linked to the detection antibody.

BOX 19-2 Monoclonal Antibodies

One of the primary tools used in many of the assays for immune function is the monoclonal antibody. Monoclonal antibodies are the product of a single B cell. To generate a monoclonal antibody, an antigen is injected into an animal, and the resultant B cells are isolated. These B cells are diluted, and a single B cell is fused with a nonsecreting myeloma cell line to form hybrids. These hybrids then produce the monoclonal antibodies highly specific for the injected antigen. In contrast, when any animal is injected with an antigen, polyclonal antibodies are generated. Many different B cells specific for that antigen release antibody, which is harvested and purified. This collection of antibodies is called polyclonal because, unlike monoclonal antibodies, it has many specificities to the same antigen. Polyclonal and monoclonal antibodies can be tagged with enzymes for fluorescence to detect the original protein antigens for which they are specific.[1]

Many proteins have monoclonal antibodies specific for them, including cell surface markers, cytokines, and even other antibodies. The quality of the monoclonal antibody can determine the sensitivity and specificity of the test used.

TABLE 19-2 Antibody Function

ISOTYPE	SERUM LEVELS*	SUBCLASSES	FUNCTION/DESCRIPTION
IgM	0.5-2.0		Secreted during initial infection; Makes large antibody-antigen complexes.
IgD	Trace		Function unknown.
IgG			Coats microorganisms, making them more likely to be phagocytosed by macrophages, dendritic cells, and neutrophils; neutralizes toxins.
	5.0-12	IgG1	Responds to protein antigens.
	2.0-6.0	IgG2	Primarily responds to polysaccharide antigens; binds poorly to Fc receptors.
	0.5-1.0	IgG3	Responds to protein antigens.
	0.1-1.0	IgG4	Response to repeated antigenic exposure; binds poorly to Fc receptors.
IgE	Trace		Binds to Fc receptors on mast cells/eosinophils and basophils to elicit allergic response; also involved in response to parasites and worms.
IgA			Provides protection at mucosal surfaces
	0.5-3.0	IgA1	Monomeric form found in blood; can trigger inflammation through FcαR1.
	0-0.2	IgA2	Dimeric form found in secretions like tears, saliva, and breast milk.

Ig, immunoglobulin.
*Serum levels presented in grams per liter.

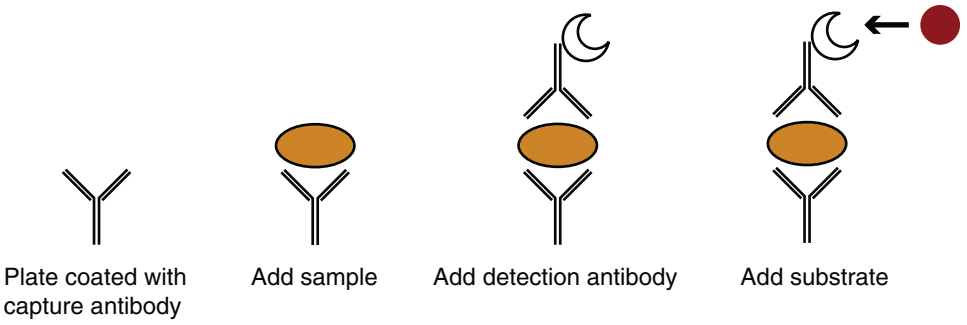

FIGURE 19-1 ELISA. A capture antibody specific for an antigen in a sample is attached to the bottom of a plate. The sample (blood, saliva, etc.) is added and excess sample is washed from the plate. A secondary antibody also specific for the antigen is added to the plate. This secondary antibody is labeled with an enzyme. When the substrate for the enzyme is added to the plate, it elicits a color change. The intensity of the color, as measured by spectrophotometry, indicates the amount of antigen that is present. Courtesy Heather Schiffke.

TABLE 19-3 **Common Autoantibodies**

AUTOANTIBODY	CLINICAL RELEVANCE
Antinuclear antibody	Systemic rheumatic diseases
Smooth-muscle antibody	Nonspecific liver damage; chronic hepatitis
Antimitochondrial antibody	Primary biliary cirrhosis
Endomysial antibody	Celiac disease; dermatitis; psoriasis
Antineutrophil cytoplasmic antibody	Vasculitis
Gastric parietal cell antibody	Pernicious anemia
Adrenal antibody	Idiopathic Addison's disease
Pancreatic islet cell antibody	Insulin-dependent diabetes mellitus
Skin antibodies	Pemphigus vulgaris; Bullous pemphigoid
Antiacetylcholine receptor	Myasthenia gravis
Antimyelin basic protein	Multiple sclerosis
Double-stranded DNA autoantibody	Systemic lupus erythmatosus
Thyroid stimulating hormone antibody	Graves' disease

Urine

When an antibody is made, the antibody light chains, κ and λ, are made in excess. These are present as free forms in serum and urine. Although small amounts of light chains are found in everyone, people with renal damage excrete higher levels of light chains in their urine. Free light chains are associated with malignant plasma dyscrasia and other lymphocyte-related immunoproliferative disorders. Intact immunoglobulin can also be found in urine.[15]

Cerebrospinal Fluid

IgG can be measured in the cerebrospinal fluid (CSF), which is important in autoimmune diseases such as multiple sclerosis.[16] Albumin can also be measured in CSF; however, albumin is not synthesized in the brain. Therefore, a comparison of IgG to albumin levels in CSF provides an indirect indication of how much IgG has been synthesized within the brain.[1]

MEASUREMENT OF COMPLEMENT AND HIGH-SENSITIVITY C-REACTIVE PROTEIN

Complement is a series of proteins that result in the destruction of microbes. Assays for complement can either be those that recognize individual complement components (such as ELISA for C3 or C4) or functional activity of complement, such as lysis. Measurement of C3 and C4 levels is sufficient, except for rare patients with genetic deficiencies, such as hereditary angioedema. Low levels of complement are more significant than high levels. For example, complement levels may be low in patients with glomerulonephritis or SLE.[17,18] However, the complement levels return to normal when patients are in remission.

High-Sensitivity C-Reactive Protein

C-reactive protein (CRP) is involved in the complement pathway. CRP functions by opsonizing bacteria, marking them for destruction by the complement cascade. Because it is readily detectable in the blood, CRP has become an important marker of inflammation. CRP is released early in infection (the first 4 to 24 hours) during the same window that many other components of inflammation are being activated. However, because it is far easier to measure than cytokines or other proteins, high levels of CRP are a more consistent marker of a recent infection.[19] Laboratories consistently offer a high-sensitivity test for CRP, called hs-CRP. This test is more sensitive than the original test for CRP, allowing detection of lower levels of CRP. Consistently high levels of hs-CRP may be diagnostic of chronic inflammation.

MEASUREMENT OF CELLS

Lymphocyte Subpopulations

T Cells

CD4T cells make cytokines that direct various arms of the immune system. CD8T cells kill infected cells. The proteins on the surface of T cells that allow them to be identified are listed in Table 19-4. To qualitatively identify T cells and separate them from other cell types, two proteins are used: CD3 and CD4 or CD8. CD3 is a signaling molecule associated with the T cell receptor and is on all T cells. CD4 and CD8 function to increase the interaction between the T cell and the antigen presenting cell. A sample of how T cells appear on a flow cytometry dot plot is in

TABLE 19-4 **Regulatory T Cells**

TYPE OF REGULATORY CELL	CYTOKINES MADE	ACTION	DEVELOPMENT OF
Treg cells (CD4+CD25+CD152+)*	TGF-β	Control overall autoimmune state?	Thymus
Type I NKT (cells) (NK cells that express a semi-invariant TCR)	Immunoregulatory Proinflammatory		Thymus
Tr1 cells (CD4+CD152+)	High IL-10 Moderate TGF-β and IFN-γ No IL-2 or IL-4	Suppress MS; suppress intestinal inflammation	Periphery systemic differentiate from Th0
Th3 cells (CD4+)	High TGFβ Low IL-4 and IL-10 No IFN-γ and IL-2	Oral tolerance	Periphery differentiate in intestinal mucosa
T suppressor cells (CD8+CD28-)	High IL-10	Suppress DC activation	Periphery

BOX 19-3 **Sample Flow Cytometry Dot Plot**

Flow Cytometry

Flow cytometry is a technique for counting cells and other microscopic particles such as cytokines and proteins. Similar to microscopy, flow cytometry allows identification of cells based on their morphology and cell surface proteins; however, flow cytometry evaluates cell populations, rather than individual cells. Cells are incubated with monoclonal antibodies specific for certain proteins on their surface. Each antibody is tagged with a different color fluorochrome. The cells are then suspended in fluid and passed through the flow cytometer. Light from lasers in the flow cytometer passes through the cells, allowing detectors on the other side to read the light scatter from the cells based on their granularity and size. The detectors also evaluate the colors of the fluorescence associated with each individual cell. The resulting data are plotted using specialized software.

Box 19-3. In healthy individuals, the CD4/CD8 ratio should be approximately 2:1. This ratio may differ in some ethnic groups.[20] CD4/CD8 ratios can be used to evaluate disease progression patients with human immunodeficiency virus infection.

When a clinician approaches a patient with suspected immunodeficiency, he or she may decide to recommend a functional test. Immunodeficiency could be caused by a cell's inability to proliferate. In this case, a lymphocyte proliferation assay or a carboxyfluorescein succinimidyl ester (CFSE) assay would be completed.

CD4 T Helper Subsets

CD4 T cells secrete discrete patterns of cytokines. Each pattern is good for different types of immune responses. A single CD4 T cell specific for a single antigen can secrete any pattern of cytokines, but will be skewed toward secreting one pattern or another depending on the initial triggering infection. CD4 T helper subsets cannot be identified by surface markers. However, because CD4 T helper subsets secrete different patterns of cytokines, intracellular cytokine staining can discriminate between subsets.

The Th0 pattern is secreted by a naïve T cell, i.e., one that has not yet seen antigen. It is the cytokine pattern that is designed to simply keep T cells alive. Th0 cells secrete interleukin (IL-2).

The Th1 pattern is secreted by T cells exposed to bacterial or viral antigens. Overactivity of Th1 T cells has been linked to many autoimmune diseases. Th1 T cells secrete interferon-γ, as well as some other cytokines.

The Th2 pattern is secreted by T cells exposed to worms and parasites, but is also involved in allergy and asthma. Th2 T cells secrete IL-4, IL-5, and IL-13.

The Th3 pattern is secreted in response to food. Because the immune response to food should be relatively inert, Th3 cells are considered a type of regulatory T cell (Treg), and are involved in immunologic tolerance. Th3 T cells secrete tumor growth factor-β.

The Th17 pattern is secreted in response to molds and extracellular bacteria. This population of T cells has recently been linked to many autoimmune diseases. Th17 T cells secrete IL-17.

Regulatory T Cells

Tregs play a key role in maintaining tolerance. The loss of Tregs is associated with disease, especially autoimmune disease. Studies of Tregs have been limited largely because of their considerable diversity and lack of unique surface markers; the current state of the science is found in Table 19-4.[21] Much of the knowledge about Tregs is from mouse models. Human Tregs have been phenotypically identified as CD4+CD25+, CD4+CD25^{high}, or CD4+CD25+FoxP3+ cells, based upon how they stain and present in flow cytometry. CD39 is another protein on the surface of Tregs that may allow reliable identification.[22] Although most CD4 T cells express CD127, Tregs display lower surface expression of this marker.[23] Tregs behave similarly to other regulatory cells, such as Th3 cells found in the gut and Tr1 cells found in the periphery, but Tregs originate in the thymus and produce different cytokines upon stimulation than these other types of regulatory cells. Activation of Th1, Th2, and Tregs can be measured with expression of CD69.[24]

B Cells

B cells are identified by the surface markers CD19 and CD20 (see Table 19-5). In addition to being markers for B cells, CD20 is a marker of non-Hodgkin lymphoma and is a current drug target.[25] Monoclonal antibodies directed at CD19 are therapeutic targets in rheumatoid arthritis.[26] The products of B cells are antibodies and can be measured as described earlier in "Measurement of Antibodies".

Monocytes and Neutrophils

Neutrophils and monocytes act early in disease. Tethered to the blood muscle walls, neutrophils are some of the first cells to reach infectious agents. Monocytes can quickly extravasate into tissues, differentiating into macrophages and joining tissue macrophages already present at the site of infection. If monocytes and neutrophils are not functioning properly, severe infections can result. It

TABLE 19-5 **Cell Markers**

ANTIGEN	IDENTITY/FUNCTION
CD3	Present on all T cells
CD4	Present on T helper cells and some dendritic cells
CD8	Present on cytotoxic T lymphocytes
CD16/CD56	Combination identifies NK cells
CD19/CD20	B cell markers
Markers of T cell activation	
CD25	IL-2 receptor; serves as a marker for Treg cells
CD28	Activation marker on CD4 and CD8 T cells
CD38	Expressed on T cells after activation; function unknown
CD39	Acts on the nucleotide base responsible for enzymatic cleavage of ATP to AMP; marker for Tregs
CD45RA	Marker of a naïve/resting T cell
CD45RO	Marker of a recently activated T cell
CD69	Early activation marker for T cells, as well as B, NK, monocytes, and neutrophils[24]
CD71	Early activation marker for T cells
CD127	α-Chain of the IL-7 receptor; absence identifies Tregs

AMP, adenosine monophosphate; ATP, adenosine triphosphate; IL, interleukin; NK, natural killer; Treg, regulatory T cells.

TABLE 19-6 **Cytokine Patterns**

IMMUNOLOGICAL EVENT	NAME OF PATTERN	CYTOKINES
Inflammation	Proinflammatory	IL-1
		IL-6
		IL-8*
		TNF-α
T activation	Th1	IFN-γ
		IL-2
		TNF-α
		GM-CSF
	Th2	IL-4
		IL-5
		IL-10
		IL-13
	Th17	IL-17
T regulation	Th3	TGF-β
		IL-4
		IL-10
	Treg	TGF-β
	Tr1	IL-10
		TGF-β
		IFN-γ

GM-CSF, granulocyte macrophage colony stimulating factor; IFN, interferon; IL, interleukin; TGF, tumor growth factor; TNF, tumor necrosis factor; Treg, regulatory T cell.
*IL-8 is a chemokine.

is rare to find patients with low functioning monocytes, because the consequences can be extreme.

When patients have severe staphylococcal or fungal infections, neutrophil numbers should be evaluated, and function should be tested. Neutropenia is more common in neutrophil dysfunction. CD18 is a consistent and reliable marker for neutrophils and can be used as a marker for flow cytometry.[27] In healthy individuals, the neutrophil count normally exceeds 1.5×10^9/L. Mild neutropenia is usually asymptomatic, whereas moderate to severe reductions in numbers are associated with a progressive increase in the risk and severity of infections. Episodes of infection are likely to be life threatening when the neutrophil count falls below 0.5×10^9/L. Neutropenia is a frequent side effect of chemotherapy.[28]

Neutrophil function consists of adhesion, migration, chemotaxis, phagocytosis, and a respiratory burst. Defects in the respiratory burst can cause chronic granulomatosis disease. One simple method to evaluate neutrophil function involves a nitro blue tetrazolium test. In this test, neutrophils ingest and reduce a soluble yellow dye to an intracellular blue crystal. Neutrophils are separated and then stimulated with endotoxin (lipopolysaccharide) and the cells are viewed microscopically.

Neutrophils and monocytes can kill microbes with a respiratory burst. Another test of neutrophil function takes advantage of this activity. Neutrophils or monocytes are incubated with live microbes, such as *Staphylococcus aureus*. After the cells have phagocytosed the organisms, they are washed to remove extracellular organisms. The cells are then lysed, and the lysate is cultured on nutrient agar. Live bacteria will grow on the agar. The number of viable organisms inversely reflects the degree of intracellular killing.

Natural Killer Cells

When cells are infected with a virus or become cancerous, they often express less major histocompatibility complex on their surface. This makes them a target for natural killer (NK) cells. NKs express surface receptors that allow them to recognize the absence of major histocompatibility complex on a target cell and kill it. In addition to this mechanism, NK cells can be identified with CD56.[29] Like CD8 activity, NK function can be measured with a 51-chromium release assay (see Box 19-3).

CYTOKINES

Cytokines are immunomodulatory molecules that play an essential role in cell–cell communication and immune reactions. They are produced by most immune cell types, and many physical symptoms of immune dysfunction are triggered by cytokines. Cytokine expression has been studied extensively in autoimmune disorders, chronic inflammation, and other diseases. Cytokine expression is most accurate when measured locally at the tissue site; however, systemic cytokine levels can be detected in serum and saliva. Cytokines may contribute to disease progression and are thus potential targets for therapeutic intervention.[30,31]

Cytokine levels can be tested with ELISA or cytometric bead array. Because clinical testing for cytokines is relatively new, clinical cytokine testing is not as validated as other forms of testing. Furthermore, cytokine levels are affected by exercise, diet, sleep, age, and gender. Cytokines tend to be secreted in patterns (see Table 19-6). Because many natural therapies can modify cytokine expression, skilled clinicians can switch people from one pattern of cytokines to another.

GENETICS

The genetic control of immunity has long been recognized. Many autoimmune diseases map to specific genetic loci. Polymorphisms in the human leukocyte antigen have been linked to insulin-dependent diabetes mellitus, multiple sclerosis, and rheumatoid arthritis. Single nucleotide polymorphisms (SNPs) in cytokine

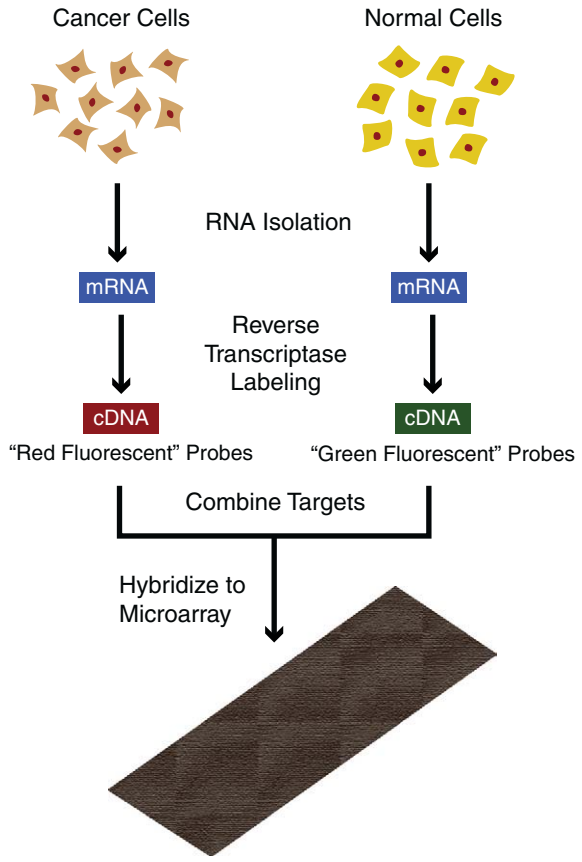

FIGURE 19-2 DNA Microarray. RNA is prepared from a collection of cells, normal and/or diseased. The RNA is translated into cDNA in vitro. The cDNA from each cell type is labeled with a different color of fluorescent dye. These cDNAs are then added to a chip or bead that has been previously hybridized with DNA probes. A computer analyzes the color of the DNA spots on the chip or bead. Relative difference in color indicates difference in gene expression between the two cell types. Courtesy Heather Schiffke.

and cytokine receptor genes are associated with the variability of immune response between individuals to infectious disease.[32] Some clinical laboratories now offer testing for SNPs. SNPs are detected using polymerase chain reaction (PCR).[33] Gene primer pairs for the candidate gene are used to amplify the DNA sequence of the patient's gene. The patient's gene is then sequenced and compared with a standard sequence.

Genetic microarray provides a second test for genetic variability and may allow clinicians to pinpoint genes that are key players in different diseases (see Figure 19-2). In addition to determining patterns of gene expression that contribute to complex disorders, microarray could elucidate gene interactions that lead to clinical symptoms or tell a physician whether a patient is responding to a therapy. Microarray involves isolating RNA from tissue, labeling it with fluorescent probe, and then comparing it with a standardized or control tissue by combining the RNA samples and hybridizing them to a chip. The color patterns are read by a computer. The expression of some genes (housekeeping genes) tends to be more stable and can act as a control. There are still several obstacles to overcome with genetic microarray technology, but clinical utility is likely.[34]

CLINICAL SYMPTOMS

It would be an oversight to exclude clinical symptoms as one of the primary ways that the immune system is evaluated. Clinical symptoms usually occur after an immune response is underway, but are often the first sign to the patient and physician that something may be amiss. Physicians recognized an immune response long before the first immune cells and proteins were discovered. The classic symptoms of inflammation: calor (heat), dolor (pain), rubor (redness), and tumor (swelling) were originally described and recorded by Aulus (Aurelius) Cornelius, a Roman physician and medical writer who lived from about 30 BC to 45 AD. These hallmarks of inflammation are caused by many complex interactions between cells and cytokines of the immune and nervous system and allow a clinician to make some assumption about immune processes without even drawing blood. For example, calor (heat) refers to fever. If a patient has a fever, a physician may assume that IL-1β is elevated. Table 19-7 illustrates which immune processes underlie the hallmarks of inflammation.

TABLE 19-7 **Hallmarks of Inflammation**

LATIN	ENGLISH	CYTOKINES AND CELLS INVOLVED
Calor	Heat	IL-1β, IL-6 act at the hippocampus, causing the body to increase blood flow, resulting in heat.
Dolor	Pain	TNF-α and IL-1β lead to localized edema that nerve endings sense as pain.
Rubor	Redness	TNF-α and IL-1β cause vasodilation and increased blood flow.
Tumor	Swelling	TNF-α and IL-1β cause increased permeability of the capillaries.

IL, interleukin; TNF, tumor necrosis factor.

Sickness Behavior

Proinflammatory cytokines act in the brain to induce nonspecific symptoms of infection. In addition to triggering fever, cytokines elicit profound psychological and behavioral changes. Sick individuals experience several symptoms, including malaise, fatigue, weakness, an inability to concentrate, and listlessness. They become sleepy (hypersomnia) and experience depressed activity and a desire to be isolated. These infection-induced changes are referred to as "sickness behavior."[35] Sickness behaviors have a variety of advantages to both the sick individual and the population at large. Malaise, fatigue, and listlessness cause a person to rest, and thus conserve energy. Rest further aids the body by decreasing heat loss, whereas shivering increases heat production. Social isolation may help prevent spread of the infection to others.[36]

Most sickness behaviors are caused by cytokines, and may help an observant clinician make a diagnosis. For example, fatigue and malaise are most commonly triggered by IL-1β. Interestingly, in some people, tumor necrosis factor-α and IL-6 may cause anger or hostility, and this emotional response leads to the social isolation.[37]

SUMMARY

Choosing appropriate immunologic tests requires physiologic, economical, and ethical considerations. To choose the right test for the patient, the reliability of the tests as well as their specificity and sensitivity must be considered. Assessing the immune system is further complicated by its sensitivity to the environment. Thus, running tests in duplicate or triplicate may be necessary to validate results.

CHAPTER 20

Intestinal Permeability Assessment

Corene Humphreys, BHSc, ND, DipMedHerb, DipHom

INTRODUCTION

The small intestine is a multifaceted organ, playing a major role in digestive and absorptive processes as well as acting as a barrier against harmful macromolecules. However, when this absorptive capacity or barrier function is compromised, the health of an individual may be adversely affected. Pathologic changes in permeability of the intestinal mucosa have been identified in a number of local and systemic disease conditions. This chapter focuses on clinical consequences that may result from a breach of gut mucosal integrity and how they relate to specific disease states. It also outlines the use of noninvasive testing to identify intestinal permeability and summarizes therapeutic options to restore mucosal integrity.

GUT MUCOSAL INTEGRITY: MECHANISMS OF DISRUPTION

A key function of healthy gut mucosa is to prevent bacteria and their endotoxins from reaching portal circulation. For this purpose, a natural physiologic barrier is formed by the mucous layer, the epithelial cells and apical junctional complex, and the lamina propria (Figure 20-1, *A*). When one or more of these components is impaired, damage to the intestinal barrier may result, allowing luminal toxins to translocate from the gut into the systemic circulation.[1,2]

The small intestine consists of specific intrinsic factors that help protect the host from environmental pathogens. These are the enterocytes as well as the paracellular spaces composed of structures called tight junctions, adherens junctions, and desmosomes (Figure 20-1, *B*). The tight junctions surround the upper portion of the lateral surfaces and the adjacent epithelial cells to create fusion points. This creates distinct fluid compartments that maintain cellular polarity and regulate the passive transepithelial movement of molecules.[3]

The tight junction zonula occludins (ZO1) is located just below the base of the microvilli and acts as the primary permeability barrier between the external and internal milieus of the body.[2] Transmembrane proteins that form part of the tight junction include the claudins and occludin families. Claudins proteins act as sealing proteins, forming ion-selective pores within the tight junction strands, whereas occludin proteins are thought to have adhesive and transducing properties. Both claudins and occludin interact with cytosolic complexes such as actin and myosin, which serve as contractile elements to open and close the paracellular junctions.[4] Transmembrane proteins can be affected by cytokines, and minor defects in the paracellular pathway can set up a vicious cycle, whereby antigen presenting cells (e.g., dendritic cells) stimulate the production of Th-1 cells that increase the production of tumor necrosis factor-γ (TNF-γ) and interferon-γ (IFN-γ) and further increase tight junction permeability.[3]

The immune system of the gastrointestinal tract also helps prevent the translocation of harmful molecules across the gut mucosa. Gut associated lymphoid tissue comprises approximately 25% of the mucosal mass of the intestine. It is considered the body's largest immune organ, containing 40% of its immune effector cells.

Gut immunity consists of two distinct mucosal defense mechanisms: the specific system and the nonspecific system. The specific system is composed of secretory immunoglobulin-A (sIgA). The nonspecific system comprises gastric acidity, motility, mucus, digestive enzymes, normal bacterial flora, and bacterial antagonism.

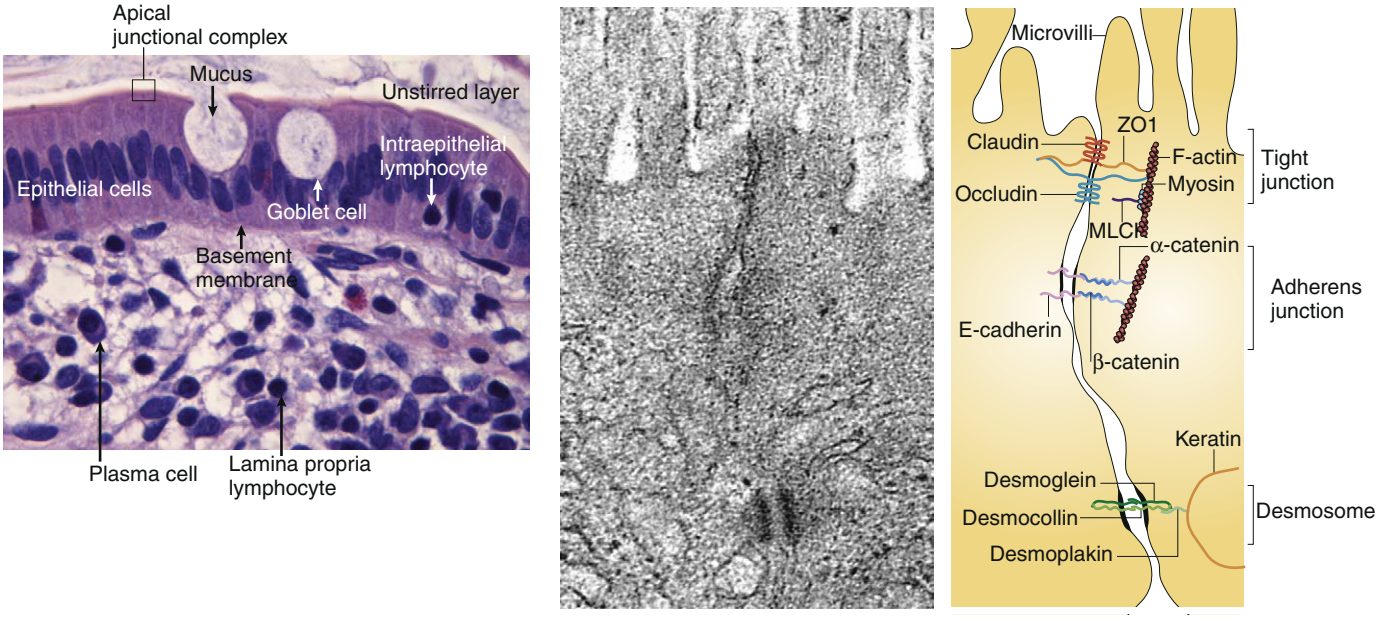

FIGURE 20-1 Anatomy of mucosal barriers. (Reprinted by permission from Macmillan Publishers Ltd. From Turner J. Intestinal mucosal barrier function in health and disease. Nature Rev Immunol 2009:9:799-809. http://www.nature.com/nri.)

Disruptions in gut barrier function may result from impaired host immunity, alterations in gut flora, or direct mucosal injury.[5]

Ordinarily, normal gut microflora provides "resistance to colonization," preventing the adherence of pathogenic organisms to the intestinal wall and their subsequent translocation.[6] Changes in gut ecology, however, can reduce this natural resistance and encourage the colonization of potentially harmful bacterial species.

Bacteria and the toxins they produce can alter membrane integrity through various mechanisms. Bacteria can secrete enzymes, such as elastase and protease, which hydrolyze the epithelial membrane and cause cells to detach from the epithelial sheet. Bacterial toxins may act on or within membranes and compromise tight junction integrity by binding to membrane receptors. Some toxins can traverse the cell membrane and inhibit cellular growth by altering protein synthesis. They may also alter membrane lipid composition, act as detergents, or form transmembrane pores. The net effect is cellular swelling, lysis, loss of intracellular constituents, and uncontrolled influx of toxic substances.[7]

Bacterial endotoxins and cytokines have been shown to impair barrier function by activating inducible nitric oxide synthase. Upregulation of this enzyme increases the amount of nitric oxide. Prolonged exposure of the cells to nitric oxide is thought to inhibit cellular respiration, decrease mesenteric blood flow, and alter intestinal permeability.[8]

Clinical Applications

Because the intestinal mucosa plays a pivotal role in immune defense and nutrient absorption, a wide variety of diseases and conditions are associated with abnormal bowel permeability (Box 20-1). Abnormal permeability is often identified through assessment of the relative rate at which two nondigestible sugars, lactulose and mannitol, permeate the intestinal mucosa. A higher lactulose-to-mannitol (L/M) ratio indicates increased gut permeability (see section on "Measuring Intestinal Permeability" on page x).

BOX 20-1 Conditions Associated with Abnormal Bowel Permeability

- Inflammatory bowel disease
- Celiac disease
- Type 1 diabetes
- Inflammatory joint disease
- Rheumatoid arthritis
- Ankylosing spondylitis
- Reiter syndrome
- Food allergies
- Alcoholism

Inflammatory Bowel Disease

To date, it is not certain if the altered intestinal permeability seen in patients with Crohn's disease is a consequence or a cause of the disease.[9] Recent research by Takeuchi et al[10] favored the notion that increased gut permeability is secondary to intestinal inflammation. In assessing healthy, first-degree relatives of patients with Crohn's disease, they found a 50% prevalence of subclinical inflammation as evidenced by an increase in fecal calprotectin (a protein marker that reflects white blood cell infiltration into the gut lumen). Expanding this data, Meddings[11] proposed a model for the development of inflammatory bowel disease (IBD) that necessitates the presence of at least three conditions: (1) an abnormal immune system that interacts inappropriately with environmental antigens, (2) the presence of an antigenic agent, and (3) a breach in gut barrier function that allows the antigen to reach the immune system.[11]

Measuring intestinal permeability in asymptomatic patients with Crohn's disease can help monitor progress and predict disease relapse. A normal lactulose recovery and L/M ratio is associated with good short-term (6 to 12 months) prognosis, whereas

increased intestinal permeability is indicative of a relapse within 6 months.[10]

Celiac Disease

Gut barrier function is altered in nearly all patients with untreated celiac disease. Intestinal permeability testing is therefore an ideal noninvasive screening test, offering a sensitivity of 89%, a specificity of 54%, and negative predictive value of 95% compared with jejunal biopsy.[12] Although jejunal biopsy is considered the gold standard for identifying celiac disease, this test is time-consuming, unpleasant, and costly, making it unsuitable as a screening tool for the general population.[13] An elevated L/M ratio helps identify which patients should undergo jejunal biopsy when clinical features are compatible with celiac disease. It can also help determine the timing of follow-up biopsy and monitor the recovery of the mucosa.[14] Impaired permeability tends to normalize within 5 months when patients strictly adhere to a gluten-free diet. Serial intestinal permeability testing can also be used to monitor dietary compliance in these patients.[12]

Diabetes

An emerging body of evidence suggests altered gut barrier function may be an etiologic factor in the pathogenesis of type 1 diabetes.[4,15-17] Bosi et al[18] assessed intestinal permeability in 81 subjects with islet cell autoimmunity, 18 of whom were in the preclinical phase, 28 with newly diagnosed type 1 diabetes, and 35 with a long-term history of the disease. The researchers found an elevation in lactulose and the L/M ratio across all groups, with the highest levels reported in the preclinical group. These results suggest that increased permeability tracks the course of the autoimmune process and precedes the clinical onset of type 1 diabetes.

Alterations in gut permeability in type 1 diabetics are thought to arise from luminal antigens, such as bovine insulin from cow's milk, gliadin from wheat, enteral viruses (e.g., enteroviruses and rotavirus), and/or disturbed microbiota. The increased antigenic load appears to activate T cells in both the small intestine and the pancreatic lymph nodes, causing β-cell damage through autoimmunity and Th-1 cytokine upregulation.[19] Type 2 diabetes does not appear to be associated with primary changes in the intestinal mucosal epithelium.[20]

Inflammatory Joint Diseases

Numerous studies have shown a correlation between different types of arthritides and increased intestinal permeability.[21,22] It is estimated that between 30% and 60% of such patients have occult intestinal inflammation.[23] To date, however, it has not been fully determined whether this correlation results from the disease process itself or is due to mucosal damage caused by treatment with nonsteroidal anti-inflammatory drugs (NSAIDs).[24-27]

Evidence for a primary cause of intestinal barrier dysfunction may be related to gut microbial infections. Specific pathogenic organisms (*Campylobacter*, *Klebsiella*, *Proteus*, *Shigella*, *Salmonella,* and *Yersinia*) have been found in patients with various arthritides who have altered intestinal permeability.[28-31] It has been postulated that gut bacterial antigens, when absorbed by the intestinal mucosa, elicit an immune response, with tissue damage occurring from molecular mimicry.[32] Measuring intestinal permeability before and after NSAID therapy in patients with inflammatory joint disease helps establish whether mucosal disruption is solely an iatrogenic response.

Food Allergies

The mucosal surface of the small intestine is the largest surface area in the body that comes into direct contact with the external environment and is estimated to be more than 200 m^2.[33] The advantage of such a vast internal surface area is that dietary nutrients can be rapidly absorbed.[34] When there is a breach of gut barrier function, dietary antigens and other luminal toxins can also be translocated across the intestinal wall. Recent research suggests that environmental factors, such as infection or stress, increase gut permeability, which in susceptible individuals can contribute to food allergies.[17]

For food allergies to manifest, intraluminal antigens must first penetrate the intestinal epithelial barrier before gaining access to mast cells in the subepithelial compartment and triggering hypersensitivity reactions. This pattern has been observed in children with atopic eczema associated with cow's milk allergy.[33] Under normal conditions, most dietary proteins are digested by gastric and pancreatic proteases and brush-border enzymes and transformed into peptides and amino acids before being absorbed by the enterocytes.[17,35] In healthy individuals, a small amount of intact proteins in the gut are taken up by enterocytes and broken down inside lysosomal compartments, which prevents undigested proteins from entering the subepithelial compartment.[35,36] In atopic individuals, CD23 (the low affinity receptor located on the apical membrane of the epithelial cell) is overexpressed, which leads to the protected transfer of IgE/allergen complexes and transepithelial passage of intact allergens.

Repeated exposure to IgE-mediated antigens places significant demands on the gut mucosa and further increases intestinal permeability, setting up a self-perpetuating cycle that maintains the allergenic state.[33,36] In addition to IgE production, the sensitization phase of allergy involves the upregulation of Th-2 cytokines (interleukin-4 [IL-4], IL-5, and IL-13).[35] In the animal model, increased production of IL-4 was found to upregulate CD23 expression. This finding may in part explain the role of IL-4 in enhancing intestinal permeability.[36]

Given the recent scientific findings, a multifactorial approach to food allergy management has been proposed; it includes allergen elimination as well as reducing inflammatory reactions and stabilizing the gut mucosal barrier.[33]

Alcoholism

Alcohol consumption can lead to pronounced changes in the ultrastructure of the epithelial layer in the small intestine. In a recent paper by Cariello et al,[37] intestinal permeability was increased in 15% to 35% of patients without cirrhosis, suggesting that altered gut permeability may be a pathogenic cofactor in the progression of chronic liver disease. A breach in gut barrier function allows gram-negative bacterial endotoxins to enter systemic circulation, contributing to the onset of portal hypertension and proinflammatory cytokine production with resultant liver damage.[38]

Factors Affecting Intestinal Permeability

A variety of treatments and conditions may impair mucosal integrity and trigger changes in intestinal permeability (Box 20-2). More recently, it was also proposed that genetic alterations in tight junction proteins might also be a precipitating factor in altered gut barrier function.[15]

BOX 20-2 Causes of Changes in Permeability

Intestinal infection
Nonsteroidal anti-inflammatory drugs
Nutritional depletion
Trauma
Chemotherapy

BOX 20-3 Gastrointestinal Infections Associated with Increased Gut Permeability

Bacterial Infections
Clostridium perfringens
Clostridium difficile
Escherichia coli
Helicobacter pylori
Vibrio cholerae

Viral Infections
Enteroviruses
Rotavirus

Parasitic Infections
Blastocystis hominis
Entamoeba histolytica
Giardia lamblia

Intestinal Infections

A number of bacterial organisms are known to interfere with the integrity of the tight junctions (Box 20-3). Exposure of the intestinal epithelia to these organisms is associated with a reduction in transepithelial resistance and disarray in the patterns of the transmembranous junctional proteins (claudins and occludin) and intracellular ZO1.[39]

Rotavirus is the most common cause of diarrhea in children and is associated with an increase in gut permeability. Repeated rotaviral infections during infancy may also increase the risk of allergy and atopy later on in life.[36]

Changes in intestinal permeability have been observed in patients with protozoan infections, specifically those caused by *Entamoeba histolytica*,[39] *Giardia lamblia,*[40] and *Blastocystis hominis*.[41] Protozoa conventionally classified as nonpathogens (e.g., *Entamoeba coli*) do not appear to alter intestinal permeability.[41]

A shift in the L/M ratio was also observed in patients with small intestinal bacterial overgrowth. Riordan et al[42] found an increase in intestinal permeability associated with an overgrowth of colonic-type bacteria, specifically *Enterobacteriaceae*, within the small intestine.

Nonsteroidal Antiinflammatory Drugs

NSAIDs are the most commonly prescribed antirheumatic drugs, and NSAID enteropathy is estimated to occur in 65% of long-term users. Even short-term NSAID therapy has been shown to cause changes in intestinal permeability similar to those seen in patients with active IBD.[43]

Ingestion of NSAIDs initially damages the enterocytes and increases intestinal permeability. The damaged mucosa is then exposed to endogenous substances, such as bile acids, bacterial products, and hydrolytic and proteolytic enzymes, which generate a chemotactic neutrophilic response. Secondary damage with subsequent bleeding and protein loss associated with NSAID enteropathy only occurs when a neutrophil chemoattractant gains access to the mucosa.[44]

Initially it was thought that cyclooxygenase-1 (COX-1) selective agents were mainly implicated in NSAID enteropathy; however, recent research suggested that long-term use of COX-2 inhibitors could lead to severe small bowel damage. It is thought that COX-2 inhibition may set up a proinflammatory immune reaction in the small intestine with subsequent mucosal damage.[44]

Nutritional Depletion

Parenteral nutrition and enteral starvation in humans have been shown to raise intestinal permeability and reduce villous height. These effects may be associated with reduced concentrations of the amino acid glutamine in the intestinal mucosa.[1]

Trauma

Patients undergoing major surgery or experiencing sustained severe trauma are more likely to have an intense systemic inflammatory response that may be followed by organ dysfunction and multiple organ failure.[45] However, patients that experience such complications often show no evidence of uncontrolled sepsis. For this reason, it has been postulated that altered paracellular permeability secondary to mucosal damage in the gut may be the etiologic factor.[46] In this theory, greater permeability results in bacterial translocation and penetration of the gut wall by intraluminal toxins, thereby initiating the secondary systemic inflammatory response.

Chemotherapy

Like hemopoietic cells, enterocytes are rapidly dividing cells that are sensitive to the effects of chemotherapeutic agents. Pledger et al[47] demonstrated a significant reduction in the absorption of mannitol and an increased L/M ratio in children treated for solid tumors. A study by Fazeny-Dorner et al[48] found an acute, transient elevation in intestinal permeability after initiation of drug therapy, with permeability returning to normal in all patients 2 weeks after chemotherapy treatment.

This toxicity to the gastrointestinal tract is an important factor that generally limits the dose of antineoplastic medication a person can receive. For this reason, monitoring intestinal permeability in patients with cancer can be a valuable means of determining the optimal timing and dosage of their medication.[49]

MEASURING INTESTINAL PERMEABILITY

Altered intestinal permeability or "leaky gut" can be assessed with a challenge test that measures the recovery of two nonmetabolized sugars: lactulose and mannitol. The different molecular weights of these sugars enable assessment of both transcellular and paracellular absorption.

Mannitol is a small molecule (molecular weight [MW] 182) that is thought to traverse the epithelium via water-filled pores in the lipid membrane of the enterocyte. Lactulose is a larger molecule (MW 342) that passes through the intestinal epithelium via the paracellular route. Diseases and treatments that alter the membrane composition and affect the tight junctions between the cells increase transport via the paracellular route.[12]

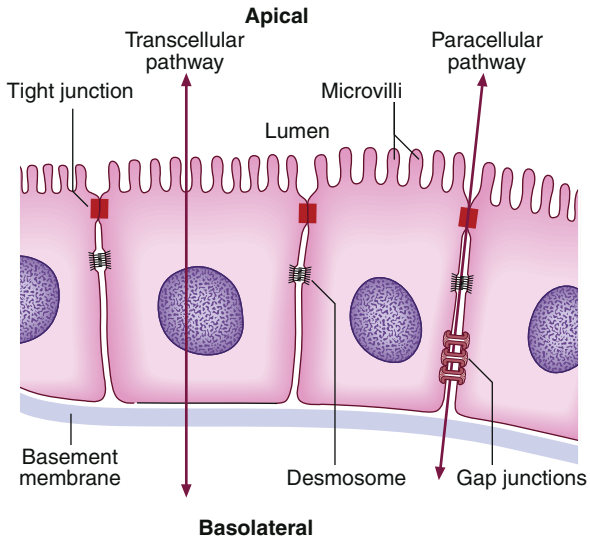

FIGURE 20-2 A sheet of epithelial cells. (From Naish J, Revest P, Court DS. Medical sciences. Edinburgh: Saunders Ltd., 2009.)

Although a number of challenge substances have been used to assess intestinal permeability, all have certain limitations. Ideally, a challenge substance should be nontoxic, completely absorbable via passive diffusion, and easily measured in urine. It should not be a substance produced endogenously, degraded enzymatically, or consumed in the diet.[15,16] Other commonly used saccharide probes to assess paracellular and transcellular pathways are cellobiose/mannitol, lactulose/rhamnose, and cellobiose/rhamnose.[50] The drawback of using cellobiose (an alternative for lactulose) is that it can be hydrolyzed by the brush-border enzyme, lactase.[13] Rhamnose (an alternative for mannitol) is incompletely excreted after an oral load.[12] Hence, lactulose and mannitol are the best documented substances for assessing intestinal permeability and most closely meet the preceding criteria for an ideal challenge substance.[17,51,52]

Because all saccharide probes are degraded by colonic bacteria, they can only provide information about the small intestine. Probes such as sucralose and chromium-ethylenediaminetetraacetic acid (Cr-EDTA) are stable throughout the entire intestinal tract and, as such, are suitable markers to assess colonic permeability (Figure 20-2).[15]

Test Procedure

The patient collects a first morning prechallenge urine sample after an overnight fast (8 hours). A premeasured lactulose/mannitol drink is then ingested, and urine is collected for the next 6 hours. The total urine volume is recorded and both samples are returned to the laboratory for assessment of the individual recovery of the two sugars and their ratio (L/M).

Interpretation

In healthy individuals, there is a 20% to 30% recovery of mannitol and less than a 1% recovery of lactulose over a 6-hour period.[12] Under pathologic conditions, the amount of lactulose permeating the intestinal barrier increases and the amount of mannitol does not change or decrease. This results in a rise is the L/M ratio, which reflects disturbances in the integrity of the small bowel.[15]

Factors That Affect the Excretion of Lactulose and Mannitol

The excretion of lactulose and mannitol depends on many factors, which can be categorized as follows:

- Premucosal factors: proper digestion, gastric dilution and emptying, intestinal dilution, transit time, and bacterial degradation
- Mucosal factors: brush-border hydrolysis, permeation pathways, and blood flow
- Post-mucosal factors: endogenous sugar production, metabolism, tissue distribution, renal excretion, and proper urine test collection

The sensitivity and specificity of the test are markedly increased if two challenge substances are used and a pretest sample is collected.[53] When both challenge substances are administered simultaneously and their ratio determined, extraneous factors such as gastric and bladder emptying, renal and hepatic disease, and intestinal motility are eliminated.[13] A pretest urine sample identifies a small percentage of patients who produce mannitol endogenously.[13]

THERAPEUTIC CONSIDERATIONS

Natural agents with the greatest evidence for their use in protecting the intestinal epithelium include the amino acid glutamine and certain probiotics. The pharmacologic agent sodium cromoglycate has good research to support its use in allergy-mediated gut permeability (see Table 20-1 for condition specific indications).

Glutamine is a preferential fuel for the small intestine and considered vital for the maintenance of mucosal growth, structure, and function.[54] It helps prevent the deterioration of gut permeability in catabolic conditions (e.g., burns, sepsis, trauma, and after major surgery).[55] Glutamine also protects against chemotherapy-induced gut permeability.[56,57] Given its role in intestinal metabolism and immunity, glutamine initially held promise as a nutraceutical for patients with IBD. However, research in this cohort is conflicting, and it is now thought that glutamine may exacerbate IBD symptoms.[55,58] Supplementation with glutamine may enhance T-cell function, which can lead to the upregulation of proinflammatory cytokines and aggravate Crohn's disease. Glutamine may also indirectly increase nitric oxide synthesis via its metabolism from citrulline to arginine, with resultant inflammation and tissue injury in patients with ulcerative colitis and Crohn's disease.[59]

Probiotics (live microbial foods beneficial to health) have been found to protect the intestinal mucosa by several proposed mechanisms (Figure 20-3).

1. They exert direct effects on the epithelium by increasing mucin and β-defensin expression and secretion, which prevents the proliferation of commensal and pathogenic organisms and restricts the movement of bacteria across the mucous layer.
2. Probiotics enhance mucosal immunity by increasing the production and secretion of sIgA, which binds to bacteria and bacterial antigens and protects against epithelial colonization.
3. Probiotics exhibit effects on neighboring bacteria by altering gene expression and/or microbiota composition and increasing commensal bacteria.

Certain probiotic strains may also produce antimicrobial factors (e.g., bacteriocins) that inhibit or kill pathogenic bacteria.[60] In addition, numerous studies have shown that probiotics can protect against epithelial tight junction alterations associated with infection, stress, and proinflammatory cytokines.[60] (See Chapters 115 and 116 for a complete discussion of prebiotics and probiotics, respectively.)

TABLE 20-1 **Therapeutic Agents for Enhancing Intestinal Barrier Function**

THERAPEUTIC CONSIDERATIONS	DOSE	STUDY DESIGN	INDICATION(S)	OUTCOMES/ MECHANISM OF ACTION
Bovine colostrum[63]	125 mL 3 times a day.	Randomized, double-blind, placebo-controlled trial.	NSAID-induced alterations in small intestinal permeability.	Prevented a 3-fold rise in intestinal permeability after short-term NSAID use. Did not influence small bowel integrity in long-term NSAID users.
Glutamine[56]	IV alanyl-glutamine dipeptide 0.3 g/kg/day for 5 days commencing on day 1 of chemotherapy.	Randomized, double-blind, crossover trial.	Chemotherapy-induced intestinal epithelial damage in patients with gastric or colorectal cancer aged 46–68 y.	Increased glutamine stores and reduced plasma endotoxin levels. (*P:* 19549287) Deficiency of glutamine is associated with a reduction in claudin-1, occludin, and ZO1.
Glutamine[57]	30 g/day for 12 days commencing on the day of chemotherapy.	Randomized controlled trial.	Chemotherapy-induced intestinal permeability in breast cancer patients aged 45–58 y.	Ameliorated chemotherapy-induced increases in intestinal permeability. Did not interfere with the antitumor effect of chemotherapy.
Glutamine[65]	30 g/day for 7 days postsurgery (taken orally or via nasogastric tube).	Randomized, double-blind, controlled trial.	Postoperative patients (abdominal surgery) aged 16–85 y.	Decreased intestinal permeability (reduced L/M ratio). Reduced serum endotoxin levels.
Glutamine[66]	30.5 g/day for 10 days (via nasogastric or jejunal tube).	Randomized, single-blind, multicenter trial.	Hospitalized critically ill patients with systemic inflammatory response syndrome aged 18–85 y.	Reduced nosocomial infection rate.
Glutamine[67]	20 g/day of alanyl-glutamine (8.18 g of alanine and 13.42 g of glutamine) administered parenterally.	Randomized, double-blind, controlled, parallel multicenter trial.	Postoperative patients (abdominal surgery) aged 44–66 y.	Decreased intestinal permeability (reduced L/M ratio), reduced hospital stay (4 days less than controls), increased glutamine stores, increased nitrogen balance.
Glutamine[68]	30 g/day for 28 days.	Randomized controlled trial.	Patients with advanced esophageal cancer who underwent radiochemotherapy, aged 56–66 y.	Decreased intestinal permeability and maintained lymphocyte counts after radiochemotherapy. Increased salivary sIgA.
Multistrain fermented milk beverage containing: *Streptococcus thermophilus*, *Lactobacillus acidophilus*, *Lactobacillus bulgaricus,* and *Bifidobacterium longum*[69]	*S. thermophilus* (20 billion CFU), *L. acidophilus* (2 billion CFU), *L. bulgaricus* (2 billion CFU), *B. longum* (2 billion CFU) administered twice a day for 4 wks.	Randomized, single-blind, placebo-controlled trial.	Diarrhea predominant IBS in adults aged 32–57 y.	Decreased small bowel permeability and improved mean global IBS scores.[69] May improve intestinal permeability by increasing the expression of tight junction proteins ZO1 and occludin (*Bifidobacterium*).[70]
Lactobacillus plantarum 299[71]	10 billion CFU/day (via nasojejunal tube) for 7 days.	Randomized, single-blind parallel trial.	Acute pancreatitis in adults aged 25–75 y.	Reduced the incidence of septic complications by maintaining the integrity of the intestinal mucosal barrier.[71] *L. plantarum* (WCFS1 strain) increases the localization of occludin and ZO1 in the tight junctions of the intestinal epithelium.[72]

TABLE 20-1 **Therapeutic Agents for Enhancing Intestinal Barrier Function—cont'd**

THERAPEUTIC CONSIDERATIONS	DOSE	STUDY DESIGN	INDICATION(S)	OUTCOMES/ MECHANISM OF ACTION
Lactobacillus rhamnosus 19070-2 and *Lactobacillus reuteri* DSM 12246[73]	100 billion CFU of each strain, administered twice a day for 6 wks.	Randomized, double-blind, placebo-controlled crossover trial.	Moderate to severe atopic dermatitis in children aged 1 –13 y.	Improved gut barrier (reduced L/M ratio).[73] Thought to work by suppressing T-helper cell proliferation, reducing proinflammatory cytokine secretion and controlling IgE-mediated responses. Increased systemic and mucosal IgA responses.[33]
Lactobacillus rhamnosus GG[74]	2.4 billion CFU/day for 5 days.	Randomized, double-blind, placebo-controlled trial.	NSAID-induced alterations in gastric permeability.	LGG protected the integrity of the gastric mucosal barrier.
Lactobacillus rhamnosus GG[75]	500 million CFU/g infant formula. 20 billion CFU twice a day (mothers).	Randomized, double-blind, placebo-controlled trial.	Atopic dermatitis and food allergies in infants. Eczema in nursing mothers.	Alleviated intestinal inflammation and promoted endogenous barrier mechanisms by reducing TNF-α and IL-4.
Saccharomyces boulardii[76]	200 mg capsules administered 3 times a day for 3 mo (400 million CFU per capsule).	Randomized, single-blind, placebo-controlled trial.	Crohn's disease in adults aged 19–54 y.	Improved intestinal permeability (reduced L/M ratio). Prevented the activation of NF-κβ and downstream proinflammatory cytokines. Inhibited the migration of CD4 + T cells and stimulated apoptosis of infiltrating cells.
Sodium cromoglycate[77]	300 mg 15 min before a food challenge.	Controlled trial.	Adults with food allergies, aged 16–65 y.	Prevented allergy-mediated changes (normal L/M ratio) after a provocation test. Reduced the allergic response by binding to mast cells and blocking the release of histamine, which prevented the synthesis of arachidonic acid mediators, such as leukotrienes and prostaglandins. Binds to other cell types, such as macrophages, monocytes, eosinophils, neutrophils, and platelets, all of which have receptors with a low affinity for IgE.
Sodium cromoglycate[78]	100 mg 4 times a day before meals.	Controlled trial.	Children with food allergies aged between 8 y and 1 mo and 9 y and 5 mo.	Reduced mast cell degranulation and prevented the appearance of IgE-IgG antigen complexes.

CFU, colony forming units; IBS, irritable bowel syndrome; Ig, immunoglobulin; IL, interleukin; LGG, *Lactobacillus rhamnosus* GG; L/M, lactulose/mannitol; NF-κβ, nuclear factor-κβ; NSAID, nonsteroidal anti-inflammatory drug; sIg, secretory immunoglobulin; TNF, tumor necrosis factor; ZO1, zonula occludins.

Other nutrients with preliminary evidence for supporting endothelial barrier integrity include: *N*-acetylcysteine, polyunsaturated fatty acids, zinc, and the polyphenols quercetin and green tea. These natural substances are thought to exert their beneficial effects by enhancing the expression of tight junction proteins.[61,62] Bovine colostrum may hold promise as a natural agent to protect against NSAID-induced alterations in mucosal integrity by downregulating proinflammatory cytokines.[63,64]

CONCLUSION

Intestinal barrier function has important implications for the etiology and pathogenesis of numerous intestinal and systemic diseases. Using lactulose and mannitol as markers to measure intestinal permeability is a safe, well tolerated, and noninvasive way to assess the integrity of the small bowel. Intestinal permeability testing can be used as a screening tool to identify patients who require further, more aggressive investigation or to assess clinical progress and response to therapy.

CHAPTER 21

Laboratory Tests for the Determination of Vitamin Status

Joseph E. Pizzorno, ND

CHAPTER CONTENTS

Introduction, *179*
Assessment of Vitamin Status, *179*
Water-Soluble Vitamins, *179*
Fat-Soluble Vitamins, *181*
Conclusion, *181*

INTRODUCTION

Laboratory assessment of vitamin status is a significant challenge for the clinician. Although measurement of blood and serum levels is easily available, their clinical value is limited to the detection of severe deficiencies. Detection of functional deficiencies requires far more sophistication.

ASSESSMENT OF VITAMIN STATUS

See Table 21-1 for laboratory tests and optimal ranges for common vitamins.[1–5]

Water-Soluble Vitamins

Ascorbic Acid (Vitamin C)

Assessment of vitamin C is particularly difficult because ascorbate readily oxidizes in assay samples. In addition, serum levels reflect recent dietary uptake rather than actual tissue levels. Recent research in an animal model of vitamin C deficiency (the *Gulo* mouse) clearly demonstrated that a dietary intake that does not lead to serum saturation of vitamin C results in tissue deficits.[6] Serum saturation of vitamin C was required to achieve tissue concentrations similar to wild-type animals, which can synthesize ascorbate. In humans, maximum serum saturation from oral dosing was predicted to be roughly 1/60th of that achieved with intravenous administration, highlighting the inability of serum levels to predict optimal physiologic function.[7,8] Leukocyte levels are not as susceptible to dietary intake but are also readily affected by infection, hypoglycemia, and many common prescription and over-the-counter drugs. The popular lingual ascorbate test does not appear to be reliable because it does not correlate well with leukocyte or serum levels. The loading test, if carefully controlled, is probably most accurate, although good standard ranges have yet to be determined. Finally, discovery of ascorbate-dependent enzymes involved in cell signaling pathways and epigenetic modulation offer the possibility for more functional analysis in the future, although unfortunately no definitive analysis is currently available.[9]

Biotin

Biotin is a vitamin B complex especially affected by oral antibiotics. Food is a poor source of this vitamin, making humans more dependent on gut flora sources. Elevation of 3-hydroxyisovalerate (3-HIA) due to deficiency of the biotin-dependent enzyme appears a useful measure. Additionally, two recent studies in which healthy volunteers were intentionally made biotin deficient suggested that elevated urinary levels of 3-HIA-carnitine might be a sensitive indicator, even for a marginal deficiency. This offers greater accuracy and is less prone to laboratory error than the traditional urinary 3-HIA.[10,11] Plasma levels of 3-HIA-carnitine may also prove to be a sensitive marker and reduce the dependency on renal function for an accurate determination, an important consideration during pregnancy.[12]

Folate

Serum folate is too greatly affected by recent consumption to be clinically useful. Homocysteine levels may be elevated because of deficiency of vitamins B_6 and/or B_{12} as well as folate. Erythrocyte folate is more accurate and considered a more reliable indicator of tissue status. Evaluation of other B vitamin status, particularly B_{12},

TABLE 21-1 **Laboratory Tests and Optimal Ranges for Common Vitamins**

NUTRIENT	TEST	ACCEPTABLE LEVEL
Water-Soluble		
Ascorbic acid	Serum	>0.3 mg/dL
	Leukocyte	30 mcg/10^8 WBCs
	Load test	0.3-2.0 mg/h in control 24-49 mg/h after 500 mg
Biotin	3-hydroxyisovalerate	<20 mcg/mg creatinine (overnight urine)
Folate	Erythrocyte folate	>160-650 ng/mL (~350 nmol/L)
	Serum homocysteine	<10 mcmol/L
Niacin	Urinary *N*-methylnicotinamide	>1.6 mg/g creatinine
	2-pyridone 5-carboxamide (2-PYR)	>1.6 mg/g creatinine
	RBC NAD/NADP	>1.0
Pantothenic acid	Urinary pantothenic acid	>1 mg/day
Pyridoxine	Serum level	>50 ng/mL
	Tryptophan load	<35 mg/24 h xanthurenic acid
	AST	<1.5 (ratio)
	ALT	<1.25
	Plasma pyridoxal 5-phosphate	>30 nmol/L
	Urinary 4-PA	>3.0 mol/d
	Serum homocysteine	<10 µmol/L
Riboflavin	EGRAC	<1.3
Thiamine	RBC transketolase	<15% increase
	Whole blood thiamine (HPLC)	>16ng/mL
Vitamin B_{12}	Serum B_{12}	>150 pg/mL
	Urinary methylmalonic acid Serum merhylmalonic acid	<5 mcg/mg creatinine
	Serum homocysteine	<0.45 mcmol/L
	Holotranscobalamin	<0.10 mcmol/L >30 pmol/L
Fat-Soluble		
Vitamin A	Plasma retinol:	15-60 mcg/dL:
	0-5 mo	>20
	6 mo-17 yr	>30
	Adult	>20
Vitamin D	25 (OH) vitamin D	40-80 ng/mL
Vitamin E	Plasma α-tocopherol	>16.2 mcmol/L
	α-tocopherol:cholestrol	>5.2 mcmol/L
Vitamin K	% serum uncarboxylated osteocalcin	<20 ? (optimal not yet determined)

Data from references 1-5.

ALT, alanine aminotranferase; AST, aspartate aminotransferase; EGOT, erythrocyte glutamic oxaloacetic transaminase; EGPT, erythrocyte glutamic pyruvic transaminase: FAD, flavin adenine dinucleotide; H_2O_2, hydrogen perioxide; NAD, nicotinamide adenine dinucleotide; NADP, nicotinamide adenine dinucleotide phosphate; RBC, red blood cell; WBC white blood cell.

may be necessary to rule out a folate deficiency. Although the presence of neutrophil hypersegmentation has been used to identify folate deficiency, this also occurs with B_{12} and iron deficiency, making it a very nonspecific marker.[13]

Niacin

Although measurement of nicotinic acid in the blood is not very reliable, measurement of its metabolites provides a clinically useful function assessment. Several metabolite tests are now available, including urinary levels of 2-pyridone 5-carboxymide and *n*-methylnicotinamide.[14,15]

Pantothenic Acid

Serum pantothenic acid does not correspond well with dietary intake, although erythrocyte levels are more closely correlated.[16] Measurement of urinary excretion of pantothenic acid appears reliable.

Pyridoxine

Several procedures are available for assessing vitamin B_6 status. Unfortunately, substantial agreement on the best methodology has not been established, because variations in phenotypes significantly alter the results of functional and loading tests. The active form of pyridoxine (pyridoxal 5′-phosphate [P5P]) is involved in some 60 enzymes, so deficient activity of these enzymes can be measured as a functional assessment of pyridoxine. Plasma levels of P5P appear to be a better functional indicator than erythrocyte levels, at least in patients with rheumatoid arthritis.[17] Plasma levels below 30 nmol/L (considered borderline deficient) have independently been associated with an increased risk for coronary artery disease, with a particularly high risk when combined with high-sensitivity C-reactive protein.[18,19] Although suitable for most circumstances, plasma P5P does not appear to be reliable during pregnancy or the acute phase of myocardial infarction, and alternatives should be used. Urinary 4-pyridoxic acid is a useful marker of recent intake only, whereas erythrocyte aminotransferase (EAST) and erythrocyte alanine aminotransferase (EALT) activation by pyridoxal phosphate may be a better indicator of long-term status.[20] Elevated homocysteine may also be a sign of deficiency, at least in some populations.[21]

Riboflavin

The most common measure of riboflavin is red blood cell (RBC) glutathione reductase activity. The enzyme is stimulated in vitro by the addition of flavin adenine dinucleotide, and expressed as erythrocyte glutathione reductase activation coefficient (EGRAC). An EGRAC greater than 1.30 is typically used as a cutoff (with higher values indicative of suboptimal status), although one recent study suggested this threshold for deficiency might need to be raised. This same study also demonstrated that riboflavin supplementation caused an increase in hemoglobin status among women with the lowest riboflavin intakes, despite no change in iron intake or absorption.[22] EGRAC is not reliable

in individuals with glucose-6-phosphate dehydrogenase deficiency. In this population, pyridoxamine phosphate oxidase may be more appropriate.[23] Blood riboflavin levels are not reliable because of technical difficulties in measurement. Lastly, homocysteine levels may be relevant for those with genetic variation in the ethylenetetrahydrofolate reductase gene. Individuals with the TT genotype of the C677 T polymorphism may have increased riboflavin needs.[24]

Thiamine

The most common measure of thiamin is erythrocyte transketolase activity. The enzyme is stimulated in vitro by the addition of thiamine pyrophosphate. Elevation in activity greater than 15% indicates a functional deficiency. The test is not reliable in patients with diabetes mellitus, pernicious anemia, or a significant negative nitrogen balance. For example, growing evidence has indicated that a tissue deficiency of thiamine exists in patients with diabetes, and may increase the risk for vascular and neurologic complications. Despite markedly reduced plasma levels of thiamine among individuals with type 1 and type 2 diabetes, erythrocyte transketolase activity remained normal, largely because of an upregulation of RBC thiamine transporter levels.[25,26] Advances in high-performance liquid chromatography technology now allow for direct measurement of either whole blood or erythrocyte thiamine, which may be a valuable alternative.[27,28]

Additionally, measurement of amino acids and their ketoacid analogues that are excreted in thiamine deficiency is being used. (See Brally and Lord[4] for a more complete discussion.)

Vitamin B_{12}

Serum levels of vitamin B_{12} are of some value, although they do not track cerebrospinal fluid levels very well, and only a small portion (20% to 30%) of total cobalamin levels are bound to transcobalamin and taken up via receptor-mediated cellular uptake. Erythrocyte cell size is also not reliable, since neurologic signs and symptoms can precede macrocytosis by 6 to 12 months.

A recent analysis found that serum levels of holotranscobalamin may be the optimal first line diagnostic procedure, at least among elderly patients. It has been suggested to be one of the earliest markers of negative B_{12} balance, and its diagnostic accuracy is not affected by renal insufficiency, a problem with total cobalamin levels and methylmalonic acid.[29,30]

Measurement of either urinary or serum methylmalonic acid is considered fairly sensitive and specific in those with healthy renal function, especially when expressed as a ratio with the urinary creatinine measurement.[31,32] Elevated homocysteine concentrations may indicate deficiency, but it is not specific to B_{12}.

Fat-Soluble Vitamins

Vitamin A

Although liver biopsy is the most accurate method of vitamin A assessment, other less invasive and less expensive methodologies are more appropriate. As with most other nutrients, serum levels of vitamin A fall significantly only after tissue reserves have been depleted, and are subject to numerous laboratory challenges as well as other factors, (e.g., infection, protein status). Serum retinol binding protein is sometimes used as an alternative to serum retinol, because it avoids many of these complications, although it is also susceptible to artificial decreases due to inflammation or protein malnutrition.[33] Optimal cutoffs have not been clearly established for retinol binding protein, although levels greater than 0.825 μmol/L have been suggested for children and greater than 1.05 μmol/L for adults.[34,35] The dark adaptation test detects early deficiency of this nutrient, and provides a useful alternative (see Chapter 26). Lastly, given the variation in the ability to convert β-carotene to retinol, the use of plasma carotene levels is probably not a useful marker of vitamin A status.[36]

Vitamin D

The widespread deficiency of vitamin D has gained a much greater degree of recognition, with most recommendations based upon 25(OH) vitamin D levels. Most functional indicators, such as levels of parathyroid hormone, point to a level of 25(OH) vitamin D greater than or equal to 80 nmol/L as being sufficient, although some evidence has suggested higher levels might be optimal, particularly for cancer prevention.[37–39]

Vitamin E

Despite dietary intake of γ-tocopherol being ten fold greater than α-tocopherol, the preference of the α-tocopherol transfer protein for α-tocopherol results in much higher serum levels, which is why the latter is often used as a biomarker. Emerging evidence suggests that despite the ease in measurement, and the widespread supplementation with α-tocopherol, mixed tocopherols (such as the γ form) is likely of greater physiologic importance.[40,41] Unfortunately, optimal levels of other biomarkers have not yet been established, although one review reported a γ-tocopherol levels range between 2 and 5 μmol/L.[42] It is also important to adjust vitamin E levels to lipid levels, such as triglycerides or cholesterol, with the latter more commonly used.

Adipose and platelet levels have been suggested to be better biomarkers, as have cells with low-density lipoprotein receptors, such as mononuclear leukocytes and buccal mucosal cells.[43]

Vitamin K

In recent years the importance of vitamin K for physiologic functions other than blood coagulation has been recognized, including functions related to both bone and vascular disease. For this reason, the traditional methods of assessment, such as prothrombin and clotting assays, may not be sufficient markers of vitamin K status, at least in regard to these other functions.[44] Better functional markers may be serum uncarboxylated osteocalcin (ucOC) levels, or perhaps a serum carboxylated OC to serum total OC ratio. One review suggested that a percent of ucOC greater than 20 is probably optimal, although genetic variations may modify this to some degree.[45–47]

CONCLUSION

As described here, many procedures are now available for the assessment of functional vitamin status. Although research continues in this important area, the reader is advised to carefully study the discussion of urinary organic acids profiling (see Chapter 28). Utilizing metabolic products excreted in the urine now allows the clinician far greater specificity in recognizing dysfunctional enzyme systems, whether they are due to genetic deviations or nutritional deficiencies.

INTRODUCTION

Lactose malabsorption results from the inability to properly digest lactose, the disaccharide found in mammalian milk. Lactase is an enzyme in the brush border (microvilli) of the small intestine responsible for cleaving lactose into absorbable monosaccharides. Lactase enzyme deficiency leads to lactose malabsorption as the gut is unable to absorb the larger diasaccharide. When symptoms such as diarrhea, bloating, flatulence, or abdominal discomfort result from this malabsorption, a diagnosis of lactose intolerance is given. Lactose intolerance affects an estimated 25% of Americans and 75% of adults worldwide.[1] As shown in Table 22-1, the condition occurs in people of all ethnic backgrounds, with a near 100% prevalence observed in Asians. Within the United States, prevalence parallels country of origin, with the highest rates in African Americans, Hispanic Americans, Asian Americans, and Native Americans.[2]

The generalized nature of abdominal symptoms of lactose intolerance can obscure proper diagnosis,[3] resulting in symptom management through medical intervention. However, when properly diagnosed, lactose intolerance may be treated with patient education, lactase supplementation, and dietary modifications,[4] eliminating the need for medical interventions. In patients experiencing symptoms, a nutritional history and objective measures of lactose malabsorption can lead to the diagnosis of lactose intolerance. Objective measures for lactose malaborption include stool pH testing, lactose tolerance testing, and hydrogen/methane breath testing. In addition, genomic tests are also available to assess the presence or absence of polymorphisms linked to lactase enzyme deficiency.

Controversy surrounds the subject of lactose intolerance stemming from the dramatic decrease in dairy consumption that can result from its diagnosis. Numerous studies showed a correlation between decreased dairy consumption and a rise in calcium-dependent conditions, such as osteoporosis, heart disease, and colon cancer.[5-10] Studies also indicated that food-based calcium was a better source of this nutrient than supplements. Because dairy foods are the richest and best-absorbed dietary sources of calcium, careful diagnosis should be made before these foods are eliminated from the patient's diet. Dietary limitation of calcium rich foods should only be done in the context of objectively proven lactose intolerance. Many patients with lactose malabsorption are able to consume moderate amounts of lactose without

TABLE 22-1 **Prevalence of Lactose Intolerance by Ethnic Group**

GROUP	PREVALENCE (%)
African blacks	97-100
Asians	90-100
North American blacks	70-75
Mexicans	70-80
Persons of Mediterranean descent	60-90
Persons of Jewish descent	60-80
North American whites	7-15
Northern Europeans	1-5

symptoms, so both the diagnosis and treatment should be pursued under professional guidance.[11]

PATHOPHYSIOLOGY

Lactose is a disaccharide that can be hydrolyzed by the lactase enzyme lactase-phlorizin hydrolase (LPH) into glucose and galactose, which are actively absorbed in the small intestine (Figure 22-1). When LPH activity is decreased in the brush border (microvilli) of the distal duodenum and proximal jejunum, then lactose malabsorption results. The presence of lactose malabsorption does not always result in lactose intolerance. Only when the amount of lactose ingested exceeds digestive capacity does lactose persist in the lumen, ultimately reaching the colon, where it may lead to osmotic retention of fluid and bacterial fermentation, thus causing the symptoms characteristic of lactose intolerance (see Figure 22-1).[12] Therefore, symptoms of lactose intolerance often require several contributing factors in addition to LPH deficiency, including (1) relatively high lactose load, (2) gut dysmotility[13] (3) rapid small bowel transit, (4) heightened visceral sensitivity,[14] and/or (5) altered bowel flora.[15]

ADULT-TYPE (PRIMARY) LACTOSE DEFICIENCY

The majority of the world's population has a normal decrease in LPH synthesis after weaning. This common autosomal recessive genotype confers the phenotype of primary lactase deficiency (lactase nonpersistence). Genetically, nucleotide sequences in the distal enhancer region of the *LCT* gene (chromosome 2), which encodes LPH, appear responsible for this developmentally programmed loss of transcription.[16]

It is theorized that maintaining the ability to digest lactose into adulthood (lactase persistence) is the result of a relatively new evolutionary genetic mutation that occurred after the domestication of farm animals.[17] Preservation of lactase synthesis has been associated with several distinct single nucleotide polymorphisms (SNPs) on the distal enhancer region of the *LCT* gene (*–13910C>T*, *–13915T>G*, *–14010G>C*). Although the presence of any these SNPs suggests lactase persistence, their absence does not equate to lactase nonpersistence, because there appear to be other SNPs that have not yet been determined.[18]

ACQUIRED (SECONDARY) LACTASE DEFICIENCY

Because LPH is located in the brush border (microvilli) of gut mucosal cells, LPH deficiency may be secondary to diseases that damage these cells. Lactose intolerance has been observed as a secondary feature in celiac disease,[19] tropical sprue, acute gastroenteritis, chemotherapy-induced mucositis,[20] cystic fibrosis, alcoholism,[21] pelvic radiation therapy,[22] and Crohn's disease.[23] In secondary lactase deficiency, treating the underlying condition and resultant restoration of mucosal integrity often restores lactase activity.[24]

CONGENITAL LACTASE DEFICIENCY

Congenital lactase deficiency is a rare inborn error of metabolism characterized by very low or absent lactase activity in the intestinal

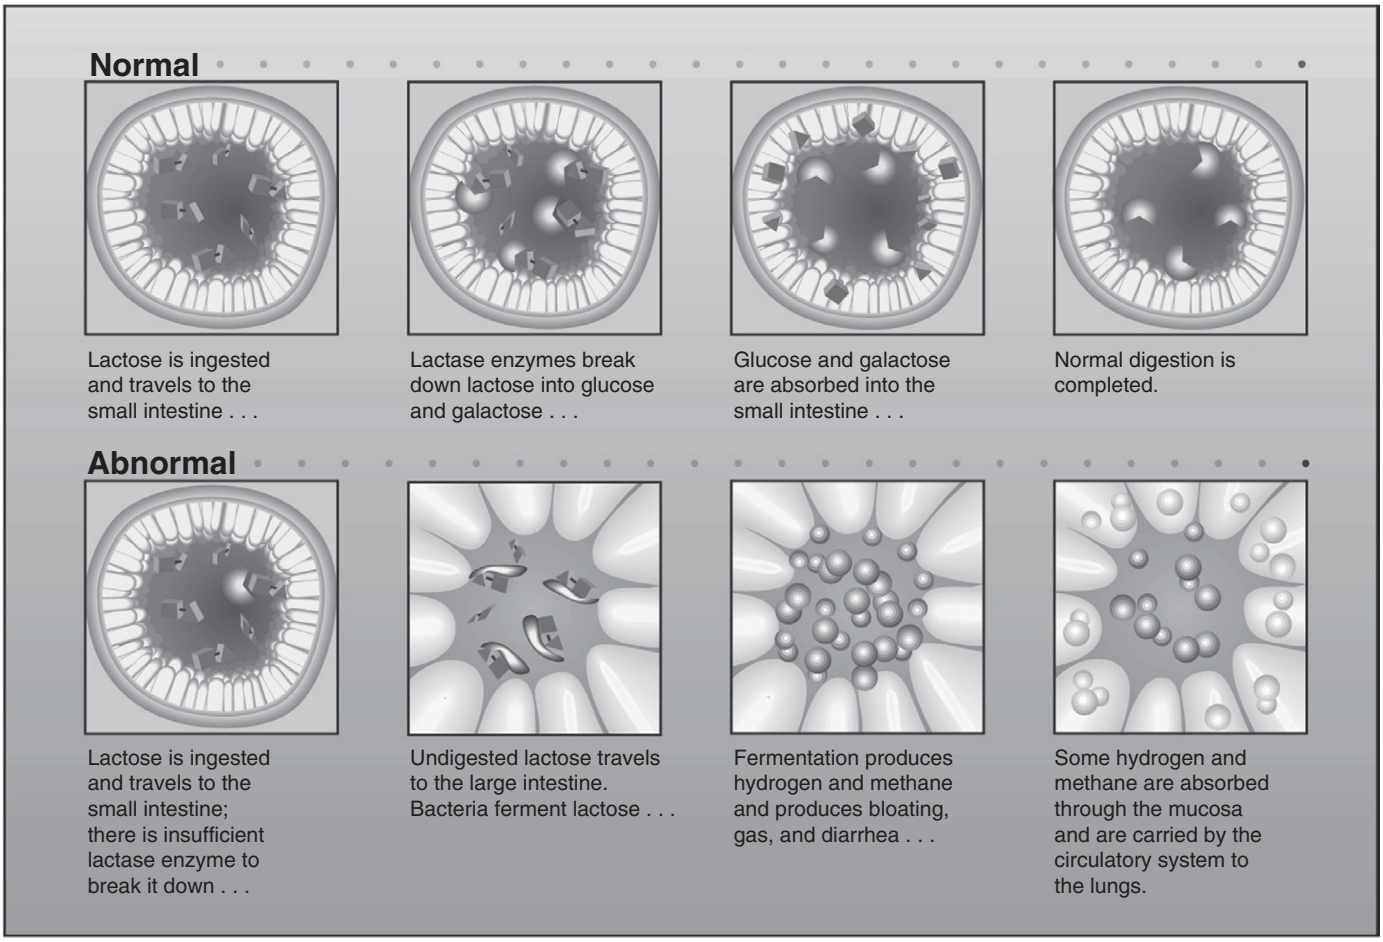

FIGURE 22-1 Lactose digestion.

microvilli at birth. Unlike lactase nonpersistence mutations, which affect upstream enhancer regions of *LCT*, mutations in the *LCT* gene itself appear to be responsible for congenital lactase deficiency.[25] Clinical symptoms include severe diarrhea, dehydration, and malnutrition, and often appear during the first week with the consumption of lactose. Separately, preterm infants may exhibit symptoms of lactase deficiency if born before 34 weeks' gestation, a condition called developmental lactase deficiency.[26] As expected, preterm infants can gain function of the lactase enzyme with time.

LACTOSE INTOLERANCE VERSUS DAIRY ALLERGY

Lactose intolerance and dairy allergy are separate pathologies. Lactose intolerance results from the maldigestion of dairy carbohydrate (lactose), whereas dairy allergy is an immune response to dairy proteins (e.g., casein, lactalbumin, whey). Dairy allergy may involve reactions (e.g., systemic anaphylaxis) that affect the gastrointestinal tract, skin, respiratory tract, or multiple systems. These immediate reactions are often mediated by immunoglobulin-E (IgE) and can cause severe morbidity and even death; however, in such cases, dietary elimination of dairy products is associated with good prognosis.[27] The prevalence of IgE-mediated allergic reaction to dairy protein in the general population is estimated at 1% to 3%, being highest in infants and lowest in adults. However, the prevalence of IgG-mediated allergic reactions may be higher.

DIAGNOSIS OF LACTOSE INTOLERANCE

Clinical suspicion of lactose intolerance should be raised when foods containing milk or milk products produce symptoms of gas, bloating, cramping, or diarrhea (Box 22-1). A short course of dietary manipulation, with careful removal of milk containing products, can strengthen the case for lactose intolerance as a diagnosis. Testing stool acidity, oral lactose tolerance testing, breath tests for hydrogen and methane, and/or genomic evaluation for *LCT* haplotypes should be used to confirm the diagnosis. Because the presence of lactase deficiency does not always result in lactose intolerance, genomic testing should never be used as a sole determinant in diagnosis. Breath testing provides the most reliable noninvasive means of determining lactose malabsorption, but must be used in the context of symptomology to make the diagnosis of lactose intolerance. In contrast, a positive breath test coupled with the absence of *LCT* haplotyping indicating primary lactase deficiency suggests a secondary causation, the diagnosis of which should be pursued.

There have been conflicting results regarding the presence of lactose intolerance in patients with irritable bowel syndrome (IBS). By definition, the diagnosis of IBS is a functional diagnosis that is made when all organic causes of symptoms have been ruled out. However, studies have shown that IBS patients have a high rate of lactose intolerance, with resolution of IBS symptoms upon lactose limitation or removal.[28-30] Rana et al[31] found that patients with diarrhea-predominant IBS had a higher incidence of lactose intolerance (82%) than patients who had either spastic-type IBS or features of both IBS types. For this reason, lactose intolerance should always be investigated in cases of IBS, a condition that affects up to 20% of Americans.[32]

A number of studies have suggested that transient lactose intolerance is also associated with infantile colic.[33,34] For susceptible children with lactose maldigestion, only 12 grams of lactose (~1 cup of milk) daily has been shown to be associated with increased abdominal pain.[35]

BOX 22-1 Symptoms of Lactose Intolerance

- Indigestion
- Bloating
- Flatulence
- Nausea
- Diarrhea
- Failure to thrive
- Abdominal cramps

Nutritional History

A detailed history of the patient's average consumption of lactose-containing food should be obtained. Often, patients do not consider yogurt, ice cream, chocolate milk, and milk ingested with cereal as important sources of lactose. They also may not be aware that lactose is added to many nondairy products to provide texture, flavor, and browning, and to absorb flavors, aromas, and food colors (Box 22-2). In addition, because of its excellent binding ability, lactose is contained in many drugs and over-the-counter products (Box 22-3). Identifying all sources of lactose is necessary to (1) identify the potential relationship between gastrointestinal symptoms and lactose consumption and (2) develop an effective lactose-free diet, if necessary.

Empirical Testing (Trial Elimination of Milk Products from the Diet)

If the patient experiences symptoms after consuming food products containing lactose, a temporary exclusion of all lactose-containing products from the diet as a preliminary diagnostic procedure may be helpful. However, diagnosis of lactose intolerance should not be based solely on elimination of milk products. This subjective test may be misleading if hidden sources of lactose (see Box 22-3) are not removed or if unrelated symptoms coincidently abate during this period.[36]

BOX 22-2 Sources of Lactose

Obvious Sources
- Milk (whole, skim, dry powdered, evaporated)
- Cheeses
- Butter, many margarines
- Goat's milk
- Half-and-half cream
- Ice cream and many sherbets
- Yogurt

Hidden Sources
- Artificial sweeteners containing lactose
- Breads, biscuits and crackers, doughnuts made with milk
- Breading on fried foods
- Breakfast and baby cereals containing milk solids
- Buttered or creamed foods (soups and vegetables)
- Cake and pudding mixes, many frostings
- Candies with milk chocolate
- Cookies made with milk
- Hot dogs, luncheon meats, sausage, hash, processed and canned meats
- Mayonnaise and salad dressings made with milk
- Nondairy creamers (except for Coffee Rich)

BOX 22-3 Prescription and Over-the-Counter Drugs Containing Lactose

Prescription Drugs	Over-the-Counter Drugs
Ativan	Actifed tablets
Bumex	Allbee C-800 Plus iron tablets
Calan	Benadryl tablets
Coumadin tablets	Chlor-Trimeton Allergy tablets
ERYC	Ferro-Sequels
Glucotrol	Imodium A-D caplets
Lasix	Marezine tablets
Lotronex	Pepcid AC chewable
Mevacor	Slow FE iron tablets
Premarin	Sudafed Plus tablets
Prilosec	Unifed Chewable tablets
Propecia	
Reglan	
Synthroid	
Vasotec	
Xanax	

Stool Testing

The fermentation of undigested disaccharides of any kind within the colon results in the overproduction of fatty acids by colonic bacteria, which lowers the pH of the stool. Normal stool pH is between 6.0 and 7.0 in young children and adults. Although infants may normally have a lower pH due to a high lactose diet, pH of less than 5.3 suggests maldigestion. Although pH testing can be used to raise clinical suspicion of malabsorption, further workup is warranted to make a diagnosis of lactose intolerance.

Breath Testing

Breath testing is the method of choice for diagnosing lactose maldigestion.[37] It is sensitive and specific,[38] simple to perform, noninvasive, and inexpensive.[36] Breath testing is based on the ability of intestinal microbes to ferment carbohydrates, in this case lactose, producing hydrogen or methane in the process. A fraction of these gases naturally diffuses from the bowel to the circulation and is eliminated via the lungs. Because there is no other metabolic production of hydrogen and methane, pulmonary excretion of these gases may be used as an indirect measure of lactose maldigestion, indicating lactase deficiency.[39]

The benefits of breath testing are as follows:

- Its results correlate strongly with the symptoms of lactose intolerance.[40]
- It can be done at home by the patient or in the physician's office.[41]
- The lower challenge dose of lactose causes significantly fewer side effects than the large doses used in blood and urine galactose tests.[42]
- The breath hydrogen/methane test is the standard in pediatric cases in which other tests would be difficult to perform.[43-45]

Historically, breath testing measured hydrogen only. However, Tormo et al[46] showed that methane is produced instead of hydrogen in some patients with lactose malabsorption. They concluded that measuring both gases was necessary for accurate diagnosis of lactose maldigestion. Other researchers suggested that although methane was produced predominantly in some cases, hydrogen production correlated more strongly with symptoms; therefore, hydrogen testing alone might be sufficient for the diagnosis of lactose intolerance.[47,48] Breath testing using a radiolabeled carbon molecule (^{13}C) in the lactose structure, showed poor correlation with lactose intolerance, as evidenced by poor $^{13}CO_2$ output by the lungs.[40]

Procedure

After an overnight fast, a baseline breath sample is collected 30 minutes after rising. The patient then ingests a challenge dose of lactose (up to a maximum of 25 grams), and breath samples are collected 1, 2, and 3 hours after ingestion of the challenge dose.[49,50]

Interpretation

If lactose maldigestion is present, breath levels of hydrogen or methane will rise within 1 to 2 hours after ingesting the lactose challenge. As little as 2 grams of carbohydrate reaching the colon produces a detectable increase in breath hydrogen.[51]

Hydrogen and Methane Responses

The normal breath hydrogen level in a healthy, fasting patient is less than 10 ppm. Patients with lactose malabsorption show an increase in breath hydrogen concentration of 20 ppm or more during the test.[52,53]

The normal breath methane level in a fasting patient is 0 to 7 ppm. An increase of at least 12 ppm of methane alone during the test is considered positive for lactose malabsorption, regardless of the hydrogen response.[54-56]

If both breath hydrogen and methane rise after a lactose challenge, the two responses are added to estimate the degree of malabsorption. The rises in breath hydrogen and methane levels together must be 20 ppm or more to suggest lactose malabsorption.[56] The extent of elevation relates to the degree of malabsorption.

False-Positive Results

False-positive results occur rarely and are usually a consequence of the following interfering factors:

- *Fiber intake.* Fiber should be avoided 24 hours before the test. Ingesting fiber in food or in supplements increases fermentation and hydrogen production.[57-59]
- *Exposure to tobacco smoke.* Tobacco smoke increases hydrogen levels and should be avoided immediately before and during testing.[60]
- *Sleeping.* Sleeping between breath sample collections may increase both hydrogen and methane levels.[61]

False-Negative Results

Breath hydrogen/methane testing has a false-negative rate of approximately 5%; the false-negative rate is 10% if only hydrogen is measured. False-negative results can occur because of the following factors:

- Use of lactase supplements.[42]
- Use of antibiotics before the test. Antibiotics decrease the bacteria that ferment lactose.[62]
- Use of laxatives or enemas before the test. These decrease hydrogen and methane responses in patients with lactose malabsorption and reduce fermentation in the colon.[63]
- Severe diarrhea or hyperacidic colon contents. Hyperacidity inhibits the production of hydrogen and promotes the production of methane by colonic bacteria.[64,65]

High Baseline Levels

An elevated baseline level of breath hydrogen indicates that one or more interfering factors are present. Testing must be repeated to obtain reliable results. A baseline breath hydrogen level greater than 10 ppm can be due to:

- Improper fasting.
- Consumption of high-fiber foods the day before testing.

- Performance of test immediately after awakening.[54]

A baseline breath hydrogen level more than 20 ppm can be due to:

- Possible small intestine bacterial overgrowth.[66] Elevated fasting levels of hydrogen occur in up to one third of patients with small intestinal bacterial overgrowth[67] and may be caused by the fermentation of endogenous brush-border glycoproteins.[68]
- Small intestine bacterial overgrowth may elevate baseline methane readings as well.[54,66,68,69]

Genomic Testing

Genomic testing requires a single blood sample and avoids the diet restrictions, lengthy collection regimen, and potential for abdominal symptoms that are associated with using an oral lactose challenge. The *LCT* gene on chromosome 2 encodes for the enzyme LPH, and wild type is associated with lactase nonpersistence. Lactase persistence is associated with two polymorphisms on the enhancer region upstream from *LCT*, C/T_{13910} and G/A_{22018}. Heterozygotes are considered to have lactase persistence but with intermediate lactase activity. Homozygotes T/T_{13910} and G/G_{22018} have lactase persistence genotype, whereas C/C and G/G homozygotes carry the wild type nonpersistence genotype. Genomic testing, although useful, only establishes a lactase enzyme deficiency, the presence of which does not always lead to lactose intolerance symptoms. Heterozygotes, although considered carriers of lactase persistence genotyping, can have bouts of impaired lactase activity due to stress or infection, rendering intermittent bouts of lactose intolerance.[70] Therefore, testing for lactose malabsorption through an objective measure of lactose malabsorption, such as hydrogen breath testing, is still warranted.[71]

Tissue Sampling

An endoscopic biopsy of the jejunum can assess the presence of lactase as well as other disaccharidases, although this test is rarely used due to the expense and discomfort involved. Morphologically, enterocytes would not show abnormality in cases of primary lactase deficiency, but may show blunting of microvilli or inflammatory changes associated with secondary causes of lactose intolerance.

Blood Testing

Lactose tolerance testing (LTT) was formerly used, but has been replaced by more sensitive breath testing as previously described. LTT required a large dose of glucose challenge, up to 50 grams, which often led to abdominal symptoms that are avoided with the lower doses used in breath testing. If the rise in serum glucose after challenge was less than 26 mg/dL during the ensuing 2 hours, then lactose maldigestion was presumed. Another similar test uses radiolabeled lactose,[13] C-lactose. Although it has been shown to have the ability to differentiate between those who can digest lactose and those with maldigestion, this method has not been evaluated for its ability to identify symptoms directly related to lactose intolerance,[66] and it is not available clinically.

OTHER TYPES OF SUGAR INTOLERANCES

Inability to properly digest other types of saccharides can produce symptoms similar to those caused by lactose intolerance. For this reason, it may be necessary to investigate other types of sugar intolerances, especially in patients whose clinical test results do not support a diagnosis of lactose intolerance. Commonly ingested sugars such as fructose, sucrose, and maltose should be considered if sugar intolerance is suspected in the presence of normal breath and genetic testing.

SUMMARY

The majority of the world's population is lactase deficient. However, lactose intolerance may not develop in all of these individuals. A comprehensive evaluation that incorporates diagnostic testing, the patient's nutritional history, and the relationship between diet and gastrointestinal symptoms is necessary for an accurate diagnosis. Proper diagnosis of lactose intolerance allows for dietary modifications that may allow a limited amount of dairy products in some lactose intolerant individuals. Exclusion of lactose containing foods altogether should be done only for those requiring strict avoidance, with careful attention to replacement of lost nutrients such as calcium. Breath testing of hydrogen/methane production after a lactose challenge is the diagnostic method of choice.

INTRODUCTION

The incidence of high-level exposure to toxic metals and acute "poisoning" is rare and is most commonly associated with occupational exposure. Associated symptoms are well defined and accepted. A plethora of published research has clearly defined many of the precise biochemical mechanisms by which specific metals elicit a vast array of adverse effects that can culminate in neurotoxicity, nephrotoxicity, cardiovascular and pulmonary disease, cancer, teratogenicity, and dysregulation of immune function. Despite knowledge of the effects of metals on the most basic biochemical processes that affect human health, the concept that "subthreshold" levels of metals in the body can negatively affect health and daily functioning is not generally accepted by the dominant medical community. However, with respect to lead, mercury, and cadmium, a consultant to the National Institute of Environmental Health Sciences stated that the margin between the levels of exposure for people in industrialized nations and the levels of exposure that are currently recognized as producing the lowest adverse effect levels is small.[1,2]

The methods for assessing metal toxicity established as standards for medical practice are best suited for detection of acute metal poisoning or recent or ongoing exposure, but do not provide an accurate estimate of the actual levels of metals that have accumulated in the body. The purpose of this chapter is to provide an overview of the various laboratory tests for the assessment of (1) exposure to toxic metals and (2) the net retention of toxic metals. It is beyond the scope of this chapter to discuss the sources and symptoms associated with long-term exposure to the most commonly encountered metals. Thorough reviews of these topics have been published elsewhere.[3-7]

The most commonly encountered toxic metals (mercury, lead, cadmium, and arsenic) are natural constituents of the earth's crust, but their increasing abundance in air, water, and surface soil results primarily from industrial demand and energy production (pollution). Consequently, the environment today has become contaminated to the point that we are all, regardless of occupation, at higher risk for at least long-term, low-level exposure to toxic metals. However, consistent with the basic principles of toxicology, confirmation of exposure is by no means valid documentation of clinically significant retention and toxicity. For a given individual, toxicity is exhibited when the level of retention exceeds physiologic tolerance, and net retention (body burden) is determined by the relative rates of toxic metal assimilation and excretion.

Two important concepts that have been largely overlooked with respect to metal toxicity may explain the discrepancies of opinion expressed by practitioners of traditional medicine and preventive medicine. The first is the potential for the combined effects of multiple toxic metals, which can have not only additive, but also synergistic, adverse physiologic effects.[8,9]

This concept should be further extended to include consideration of the potential combined effects of toxic chemicals and toxic metals, the total toxic load. The broad heading of toxic chemical entities includes not only naturally occurring and synthetic exogenous compounds but also noxious endogenous compounds derived from a severely dysbiotic or poorly functioning gastrointestinal (GI) system. The second is the remarkable individual variability in susceptibility or tolerance to toxic metals. Established precedence for the phenomena has been provided by such observations as the rapid contact allergic response that is elicited by mercury in a small percentage of a population.[10] Individual variability in susceptibility is determined in part by genetic polymorphisms, nutritional status, and the total toxic load.[7,9]

The factors of multiple toxins and individual variability impede simple interpretation of any test result for an individual patient.

No single perfect test is available for the diagnosis of chronic metal toxicity; any test result must be interpreted in conjunction with a thorough review of a patient's physical findings, exposure history, and symptoms. However, the symptoms associated with a chronic toxic metal retention appear to be diverse and rather nondescript, and they may not be fully expressed until later in life. Clear examples of such latency of symptom expression have been provided for lead and hypertension[11] and cardiovascular mortality.[12] Therefore, to address the needs of clinicians who focus on preventive medicine as opposed to crisis management, the following review of laboratory tests emphasizes testing that has greater sensitivity with respect to detection of the bioaccumulation of the most commonly encountered toxic metals. Emphasis has been placed on the distinction between testing that is most appropriate for assessment of exposure versus net retention.

ASSESSMENT OF TOXIC METAL EXPOSURE

Hair Elemental Analysis

When performed properly, hair elemental analysis can serve as a qualitative screening test for exposure to toxic metals, but it is not a reliable method for the diagnosis of metal toxicity. Hair is an excretory tissue that can provide a chronologic record of bioavailable trace elements in the body, and the hair content of mercury, arsenic, lead, and thallium has been used as evidence for the cause of death.[13] Once metals are incorporated into growing hair, there is no back exchange into the body; therefore, the concentration of metals in hair is usually far greater than that in blood or urine. The length of the hair specimen analyzed dictates the duration of time during which exposure occurred, and segmental analysis of hair can be used forensically to estimate the chronologic course of exposure. A study of the lead and mercury content of hair from a long-deceased president of the United States was performed at the Armed Forces Institute of Pathology in Washington, DC, exemplifying the potential utility of hair analysis for exposure to toxic metals.[14] Detection of toxic metals in hair actually predates that in blood and urine.[15]

A growing number of peer-reviewed publications support the value of elemental analysis of hair specimens for the detection of exposure to toxic metals. For example, elevations of arsenic in both hair and urine confirmed arsenic exposure from a pesticide in an individual with peripheral neuropathy and macrocytosis.[16] Hair levels of lead, manganese, cadmium, and other toxic metals have been correlated with psychological conditions and deviant or violent behaviors.[17] Lead, cadmium, and mercury levels in children's hair have been correlated with childhood intelligence. Hair analysis has been used to identify historical as opposed to current exposure to lead.[18] School children with relatively high levels of lead in their hair had slower reaction times and less flexibility in changing their focus of attention than children with relatively low concentrations of lead in hair.[19]

The Agency for Toxic Substances and Disease Registry (ATSDR), the U.S. Environmental Protection Agency, and the National Academy of Sciences recognize the scientific validity of hair mercury levels as an indicator of maternal and fetal exposure to methylmercury. In a cognitive performance study of children in the Faroe Islands, there were detectable effects on brain function in the children whose mothers had elevated levels of hair mercury.[20] History of fish consumption and mercury in hair samples are considered the best indicators of human exposure to methylmercury.[21] Fish consumption among Scandinavian[22] and Tyrrhenian men,[23] Amazonian children,[24] and people from the Minamata Bay area[24] was positively correlated with hair and blood mercury levels. Note that hair elemental analysis definitely provides useful information about exposure to methylmercury (fish consumption); however, it is not nearly as useful for disclosing information about exposure to inorganic mercury as derived from dental amalgams.[24] The concentration of methylmercury in hair is about 300 times higher than that in blood.[25] In sharp contrast, about 75% of total hair arsenic is present in the inorganic form.[26]

Although an increasing number of peer-reviewed reports support the clinical utility of elemental analysis of hair for the assessment of exposure to specific toxic metals, some considerations prevent its acceptance by governmental agencies in the United States. In June 2001, the ATSDR convened a panel of scientists with some expertise in hair analysis or risk assessment to explore "the state of the science of hair analysis."[27] Overall, the discussion was objective and focused on the existing scientific data. A summary statement from the meeting concluded, "In general, hair analysis results can provide limited qualitative insights into environmental exposures and rarely can answer questions about potential health effects."[28] Primary concerns raised by the group pertained to uncertainties about the quantitative relationship among the actual "internal dose," the rate of incorporation into hair, and the current lack of well-established data to enable one to predict potential health effects for a given concentration of a specific metal in hair. Over interpretation of the results of elemental analysis of hair is a serious concern shared by science-based laboratories and astute clinicians as well as the ATSDR. It should be kept in mind that the ATSDR has been interested in the use of hair analysis as an initial screening tool for inexpensive exposure biomonitoring of groups of people who are exposed to toxins at suspected sites of contamination. The goal of the ATSDR to be able to use hair elemental analysis as confirmation of toxicity is quite different from the use of the procedure in preventive or comprehensive medicine simply to provide an initial indication of exposure.

The consensus report by the ATSDR is consistent with the aforementioned statement that hair analysis can provide some qualitative information about exposure to toxic metals but does not provide a basis for diagnosis of metal toxicity. As such, hair analysis may be helpful to clinicians as a step toward identifying potential health problems that may be associated with toxic metal exposures before significant symptoms are expressed. Further testing should be performed before treatment options are considered. The clinician should be wary of laboratories that perform hair analysis as a vehicle to sell nutritional supplements and should be aware of interlaboratory variation.[29] Clinicians are recommended to use only laboratories that can validate their certification or accreditation and incorporate state-of-the-art methodologies for washing, digesting, and analyzing hair specimens.[30] Appropriate quality control characteristics and the validation of the establishment of reference ranges, accuracy, precision, and reliability of state-of-the-art hair analysis have been described.[31-33]

Blood Analysis: Toxic Metal Exposure

For the most commonly encountered toxic metals, the current standard for diagnosis of metal toxicity is abnormally high concentrations in whole blood or urine. However, blood analysis for toxic metals is a better indicator of exposure than toxicity in most cases. Distribution of metals, such as lead, in the body has been long recognized as initially dependent on the rate of delivery via the blood to various tissues and organs.[34] Subsequent redistribution then depends on the relative affinities of tissues for the metals

and toxicodynamics, which can vary markedly among individuals. Tissue affinities for metals are determined in large part by the high relative intracellular concentrations of reduced glutathione and metallothionein.[35] Further, blood levels can fluctuate considerably with intermittent exposure and assimilation. Thus, as stated by the ATSDR/Centers for Disease Control, the concentration of lead in blood reflects mainly the exposure history of the previous few months and does not necessarily reflect the larger burden and much slower elimination kinetics of lead in bone.[9]

Examining kinetic models of metal metabolism shows that the blood metal compartment has the shortest biological half-life. Metals leave the blood by excretion (urine, bile, and sweat) and transfer to tissues. The retention by tissues, such as bone, kidneys, and brain, accounts for the much longer biological half-lives of most toxic metals in the body. This simple concept has been obviated in studies presented in the *Physician's Desk Reference*.[36] Adult and pediatric patients who were diagnosed with lead toxicity on the basis of elevated blood lead values exhibited marked reductions in blood lead levels after chelation therapy with succimer. However, 2 weeks after cessation of chelation, blood lead levels rebounded between 60% to 85% of pretreatment levels (the rebound effect was associated to some degree with all pharmacologic chelators). The relationship between blood lead levels and the quantity of lead excreted in urine after calcium ethylenediaminetetraacetic acid (Ca-EDT) or succimer chelation was nonlinear, in that arithmetic increases in blood lead were associated with exponential increases in lead excretion.[1,37]

The correlation between blood lead and chelatable lead is poor in adults with previous exposure.[1]

Under extreme conditions of massive accumulation of metals (long-term occupational exposure), the equilibrium between tissue stores and blood can result in blood metal levels that are at or above the established threshold values for the diagnosis of metal toxicity but still do not indicate the extent of total body retention. The current gold standard of blood lead measurement for assessment of lead toxicity in children is disturbing: no minimum response levels have been established for lead because a threshold has yet to be defined for the most sensitive effect of lead neurotoxicity.[38]

Interestingly, fractionization of blood into the plasma versus red blood cell compartments can provide valuable information to the clinician about the primary sources of exposure to mercury. Approximately 95% of methylmercury, most commonly derived from contaminated fish, is associated with red blood cells,[39,40] whereas about 90% of inorganic mercury (amalgams, occupational exposure) is found in the plasma compartment bound to albumin, cysteine, and nonspecific proteins.[40] Because the first step in successful detoxification is to remove the source of exposure, documentation of the primary source of exposure to mercury can be instrumental for efficient detoxification. Blood arsenic levels, albeit with a very short half-life (approximately 6 hours), reflect exposure to inorganic arsenic and methylated metabolites of arsenic, but not dietary arsenic (shellfish), which is rapidly excreted in the urine.[41,42]

The analysis of whole blood, plasma, and red blood cells can provide valuable information about exposure to specific forms of some metals without the need for expensive determination of subspeciation.

Urinalysis of Toxic Metals: Unprovoked

In general, and despite the current standards for medical care, urinalysis for toxic metals does not provide a scientifically valid basis for diagnosis of metal toxicity. However, in some cases it provides an indication of recent or ongoing exposure to certain metals.

Such is not the case for lead, because urinary lead is generally not a useful biomarker to estimate low-level exposure to lead. However, elevated urinary lead–chelate complexes resulting from the Ca-EDTA mobilization test provide a good means to assess increased lead retention.[9]

A different scenario exists for organic arsenic as well as inorganic and organic mercury. The most commonly accepted biomarker for exposure to inorganic mercury is the urinary level of inorganic mercury.[43] However, the World Health Organization (WHO) standard for occupational exposure is very high (50 mcg/g creatinine).[44] This high standard has been challenged because neurologic impairment has been reported for occupationally exposed subjects[45,46] whose urinary mercury levels were well below the WHO standard. Evidence that urinary mercury levels are indicative of exposure to implanted mercury amalgams has also been published.[47] In a study of 1127 Vietnam-era veterans reported by the National Institute of Dental Research, a highly statistically significant correlation was detected between the level of amalgam exposure and urinary mercury levels, although mean urinary mercury levels were only about 2 mcg/g creatinine. Several other studies have reported an association between amalgam exposure and urinary mercury levels.[48-51] Elevations of urinary arsenic have been detected in workers during periods of occupational exposure, including copper smelting, spraying of insecticides or herbicides, and application of wood treatments.[52]

Arsenic can be markedly and transiently elevated in individuals within 48 hours after consumption of shellfish that contain high levels of relatively nontoxic species of organic arsenic.[53] Urinary mercury is frequently elevated in people who consume high levels of fish.[22,54] Therefore, analysis of an unprovoked urine specimen is highly recommended to avoid alarmism and confounding the interpretation of the results of a urinary metals provocation test, and patients should be instructed to abstain from the consumption of fish and shellfish for about a week before a chelation challenge is performed. Elevated urinary values of arsenic and mercury associated with the specific dietary and occupational conditions reflect recent or ongoing high-level exposure, but are not necessarily reflective of the body burden of the specific metals. Although blood metal levels reflect transient transport in the body, urinary levels qualitatively reflect excretion of an unknown fraction of the total body pools of assimilated metals.

Urinalysis: Biomarkers of Renal Toxicity

Toxic metals such as cadmium, mercury, and lead are known to be nephrotoxic at high levels of assimilation. Cadmium is of particular concern because of its exceedingly long residence time in the kidneys.[55] Therefore, in addition to urine levels of cadmium, urinary biomarkers of renal damage should be assessed for documentation of cadmium toxicity. Early markers of cadmium-induced renal damage include proteinuria, glucosuria, aminoaciduria, hypercalciuria, and polyuria.[56] Sensitive urinary biomarkers for more advanced cadmium-induced tubular damage include elevated levels of the low-molecular-weight protein β_2-microglobulin, retinal-binding protein, and *N*-acetyl-β-D-glucosaminidase (NAG).[57] Abnormal urinary levels of NAG have also been reported in association with markedly high urinary mercury levels (35 mcg/g creatinine) in chloralkali workers with long-term exposure to inorganic mercury.[58] It is noteworthy that the urinary NAG levels were correlated with urinary mercury and integrated dose of exposure but not with concurrently measured blood mercury levels.[57] Thus, it appears that assessment of urinary biomarkers of renal damage may be useful in the diagnosis of toxicity in cases of very high exposure

to cadmium and perhaps mercury. However, negative findings for the renal biomarkers do not exclude the possibility of chronic low-level metal toxicity that is most commonly encountered in general clinical practice.

ASSESSMENT OF RETENTION: URINALYSIS, PROVOCATION TESTS

The best currently available method to estimate the level of retention of toxic metals in the body is urinalysis for toxic metals after the administration of a chelating agent. In the 1970s, the value of a standardized calcium-disodium EDTA (Ca-Na_2-EDTA) provocative test was recognized as sensitive to determine the mobile and potentially toxic body lead stores, and to assess response to chelation therapy in pediatric patients with high blood lead levels.[59–61] Subsequently, Markowitz and Rosen[62] described the results of a comparable, yet more convenient test that would permit use in a greater number of qualifying patients.

The concept and value of using metal complexing agents to estimate the body burden of readily available tissue depots of other toxic metals have gained increasing acceptance in the United States, and currently, several other pharmaceutical agents are widely used for this purpose. The most commonly used pharmaceutical agents are Ca-Na_2-EDTA, Dimaval,-(R,S)-2,3-dimercapto-propropane-1 sulfonate (DMPS), and meso-2,3-dimercaptosuccinic acid (DMSA). Nonpharmaceutical compounds that have also been utilized as possible provocation agents include *N*-acetyl-cysteine (*N*-AC) and potassium-citrate (K-citrate). The latter compounds are not chelators by definition and have not been studied extensively.[63]

EDTA

Ca-EDTA has been approved by the U.S. Food and Drug Administration (FDA) and used intravenously for many years as the provocation agent and therapeutic agent of choice for patients with high blood lead levels. The compound is also well known to be effective for increasing the urinary excretion of iron, copper, nickel, cadmium, and manganese.[64] Ca-EDTA also has a high affinity for zinc and, if not used properly, can cause zinc deficiency. The maximum recommended Ca-EDTA (50 mg/ kg, ≤ 3 g) infusion rate is 1 g/h, and clinicians are strongly encouraged to assess glomerular function before use (Ca-EDTA mobilized metals are excreted in the urine). Before attempting to embark on the safe and effective use of Ca-EDTA, clinicians should attend specific training courses. Although the "slow-push" Ca-Na_2-EDTA protocol introduced in the United States appears to be effective for increasing the urinary excretion of lead,[65] it has not been formally evaluated for safety. Ca-EDTA is not nearly as effective a chelator of mercury as are the dithiol chelators. Therefore, this chapter focuses on the metal complexing agents that are newer to the United States, the dithiol agents DMPS and DMSA.

DMPS

DMPS appears to be the most productive agent for the mobilization of mercury, as determined in vitro[66] and in a comparative study during the Iraqi mercury crisis, in which people were acutely poisoned after consumption of grains contaminated with a methylmercury-containing fungicide.[67] More relevant to the typically encountered clinical situation, a DMPS provocation study was conducted with volunteer college students.[68] Subjects with and without amalgam fillings were given 300 mg DMPS (orally), and all urine was collected over the subsequent 9 hours. DMPS raised mean urinary mercury for the nonamalgam group from 0.27 to 5.1 mcg and that of the amalgam group from 0.7 to 17.2 mcg over the 9-hour period. A highly significant positive correlation was detected between the amount of mercury excreted after the DMPS challenge and amalgam surface area.

An additional study supports the value of provocation testing for people occupationally exposed to mercury vapors. A comparison of urinary mercury levels was made before and after oral administration of a 300-mg dose of DMPS to dental technicians, dentists, and nonoccupationally exposed controls.[49] Unprovoked urine mercury levels were comparable for dental technicians and dentists and were about five times higher than those in controls. Compared with prechallenge values, DMPS-induced urinary mercury (micrograms per 6 hours) increased by a factor of 87, 49, and 34 for the technicians, dentists, and controls, respectively. Post-DMPS urinary mercury levels were 16 and 6 times higher than in controls for the technicians and dentists, respectively. The group mean urinary mercury for the technicians after DMPS was 424 ± 85 mcg/6 h. Baseline urinary coproporphyrin levels, which are biomarkers of aberrant heme biosynthesis, were significantly correlated with urinary mercury levels after DMPS but were not correlated with baseline urinary mercury levels. The researchers concluded that post-DMPS urinary mercury levels were better indicators of exposure and retention than unprovoked urinary mercury levels.

The pharmacokinetics of DMPS have been well defined,[69,70] and the efficacy of DMPS for detoxification of mercury,[71] arsenic,[72] and lead (pediatric)[73] have been documented. Although DMPS is not approved by the FDA, it is registered in Germany with the German Drug Regulatory Authorities and is available in the oral form without prescription.[69] In the United States, DMPS is available by prescription only from compounding pharmacies for oral and IV or intramuscular injection. Slow infusion (approximately 10 minutes) is recommended when giving DMPS IV (3 to 5 mg/kg, not to exceed 250 mg) to avoid hypotension. Because DMPS is not an FDA-approved drug but is permitted to be compounded for use by physicians, the clinician is advised to obtain a signed informed consent form from each patient before administering DMPS. DMPS is associated with a very low incidence of serious side effects,[69] and its safety in general was evident from the observations made during the course of extensive IV administration (250 mg every 4 hours for 12 consecutive days) in a young woman who had severe arsenic toxicity.[72] The most commonly reported side effects associated with DMPS are nausea, weakness, vertigo, chills, fever, cutaneous reactions/itching, erythema multiforme, and elevations of transaminases.[70,72,73] An extensive review of the German literature about the pharmacokinetics, affinities for various metals, and side effects of DMPS is available.[73]

A detailed description of an extensively used oral DMPS provocation protocol has been presented,[69] as well as an intravenous DMPS provocation protocol.[5] To establish the basal urinary rate of metal excretion, the patient is instructed to fast overnight and to collect a urine specimen. In the morning, with an empty stomach and after the bladder is emptied, the patient is given 300 mg (or 10 mg/kg) DMPS orally, and all urine is collected for the subsequent 6 hours.[69] A light meal (no seafood or fish) may be consumed after about 2 hours, and fluid consumption is encouraged. The specific laboratory instructions should be followed for preserving and shipping the specimen. Metals mobilized by DMPS are excreted primarily by the kidney and to a much lesser extent by the liver (biliary/fecal).[69] A thorough discussion of mercury detoxification protocols based on clinical experience has been presented.[5]

Equilibrium and stability constants (in vitro) for various DMPS-metal complexes have been presented.[74] In the clinical setting, DMPS is effective for the mobilization and excretion of bismuth, mercury (organic and inorganic), copper, lead, arsenic, antimony, nickel, tin, tungsten, and gold but does not affect aluminum or uranium excretion. In the majority of adult patients, mercury is the predominant metal excreted after DMPS, and elevation of copper is normal. As mercury levels decline during detoxification therapy, it is common to see increased urinary levels of other metals, such as lead and tin, with subsequent challenges. The shifting pattern of metal species excreted is based on a combination of affinities of DMPS for the different metals as well as on mass competition for metal binding sites. There are no well-established guidelines for the interpretation of the results of the DMPS challenge test. Therefore, conclusions about toxicity cannot be made from the DMPS test results alone. Consideration has to be given to the overall medical examination, medical and exposure history, and presenting symptoms. If a decision is made to proceed with some form of detoxification therapy, the initial challenge result can serve as a reference point against which subsequent challenge results can be compared to evaluate the efficacy of treatment. The levels of other toxic metals excreted should always be considered, and one should note that DMPS does not provide direct information as to the level of mercury present in the central nervous system. It is beyond the scope of this chapter to discuss protocols for metal detoxification, but it is emphasized that if a pharmaceutic metal complexing agent is to be used, glomerular filtration rate must be assessed before initiation of chelation therapy.

DMSA

Another dithiol metal complexing agent, DMSA, is also widely used for provocation testing, as well as detoxification therapy for lead, mercury species, and other sulfhydryl reactive metals (e.g., arsenic, antimony). Several studies demonstrated the effectiveness of DMSA to increase the urinary excretion of lead[75-77] and mercury and decrease the blood levels of these metals.[37,78-80]

DMSA was approved by the FDA for lead detoxification and is an agent of choice for lead detoxification in children and adults. DMSA is available only for oral administration, and only about 20% of orally administered DMSA is systemically available after a single dose.[36] DMSA, when used in conjunction with Ca-Na_2-EDTA, increases cumulative urinary lead excretion and ameliorates redistribution of lead and mercury to soft tissues.[81,82] DMSA is restricted to the extracellular compartment[69] and does not appear to cross a healthy blood–brain barrier. In rodent models, however, DMSA has been demonstrated to be effective in decreasing the levels of lead and mercury in the brain.[78,83-85] Animal studies also indicated greater efficacy of DMSA for lead detoxification when the compound was concomitantly administered with antioxidants.[79,80] This is the case for all bona fide metal complexing agents. However, the antioxidants lipoic acid and *N*-AC alone had no effect on lead excretion. To date, no reliable studies have been published to indicate that lipoic acid is an effective metal-binding agent that has a net effect on metal excretion in humans, and the potential for lipoic acid-induced mercury redistribution, particularly to the brain, is a significant consideration.[86]

DMSA is generally well tolerated with common but mild side effects, including GI bloating and/or gas, occasional loose stools, and skin rash. Assessment of liver enzyme levels is recommended before and periodically during extended administration. Compared with DMPS and Ca-EDTA, DMSA has minimal effects on essential elements such as copper and zinc, but DMSA is excreted primarily as a mixed disulfide with two molecules of cysteine.[87] Thorough reviews of the pharmacokinetics and clinical use of DMSA have been presented.[5,69,70,88] It should be noted that there is a tremendous difference between the DMSA protocol described for acute lead poisoning[77] and that commonly used for chronic lead retention.

Various protocols for DMSA provocation testing have been suggested.[5,89] However, a convenient and productive provocation protocol has been described that entails giving a single dose of DMSA orally (30 mg/kg, not more than 2 g) on an empty stomach and collection of all urine for the subsequent 6 hours.[63] The peak rate of excretion of metals occurs after about 3 hours. The protocol is well tolerated, enhances compliance, and significantly reduces exposure to the compound. However, the potential for a single large dose of DMSA to leave behind some metals that have been mobilized but not excreted should be considered. It may be beneficial to continue to give DMSA at the standard treatment dose of 5 to 10 mg/kg three times daily for the next day or two to "clean up" metals that may have been left behind. Patients should be advised in advance that their urine will transiently have a foul, sulfurous odor and transient GI inconvenience may occur.

Nonpharmaceutical Agents

Nonpharmaceutical compounds, such as *N*-acetyl-L-cysteine (*N*-AC) and potassium citrate (K-citrate) have been tested for efficacy as provocation agents for mercury in one published study.[63] Urinary mercury levels, expressed as micrograms per liter, were compared before and after a single oral dose of *N*-AC (30 mg/kg), K-citrate (5 g in 200 ml water), DMSA (30 mg/kg), or DMPS (Unithiol, 250 mg in 5 ml water). Basal urinary mercury levels (about 5 mcg/L) were comparable for all of the treatment groups, each of which contained 16 to 65 polysymptomatic subjects. All subjects either had dental amalgams or had recently undergone removal of amalgams. Urine was collected for 3 hours after the challenge compounds were given, except that urine was collected for only 2 hours after the DMPS. The different collection time for the DMPS prohibits valid comparisons of the effects of the other agents with that of DMPS. The high bolus doses of *N*-AC and K-citrate significantly increased urinary mercury, by 131% and 83%, respectively, compared with basal values. Under these conditions of different collection times, DMSA and DMPS increased mercury excretion by 163% and 135%, respectively. No mention was made of the urine volumes associated with the different test groups, and clearly, the data would have been easier to interpret had the results been standardized per gram urinary creatinine.

Grossly misleading values for urinary metals can be associated with expression of excreted metals per unit volume because urinary output can vary considerably. No other data are currently available to permit further evaluation of the value of the nonpharmaceutic compounds as provocation agents. These two compounds also should be tested in animal models to determine whether they are associated with significant redistribution of metals among various tissues, because neither is a true chelator and their stability constants are relatively low. Currently, no definitive studies are available to assess the utility of parentally administered reduced glutathione as a metal complexing agent. As a final note about other routes of administration of various authentic and potential metal detoxification agents, particularly with respect to provocation testing: the author has not been able to find any published research addressing the systemic bioavailability or efficacy of any agent that is given via a transdermal delivery system.

FECAL METALS ANALYSIS

Several toxic metals, including mercury, lead, thallium and cadmium, are naturally excreted primarily or partially in bile. Therefore, under certain conditions analysis of fecal metals, without provocation, may provide at least qualitative information about the rate of biliary excretion of assimilated metals. However, contaminated foods present a significant source of exposure to metals, and metals that have not been assimilated by the GI tract can contribute to a significant percentage of the total amount of metals measured in a fecal specimen.

In addition to dietary contamination, fecal mercury is very much influenced by the amount of mercury that is present in the mouth in the form of mercury amalgams.[90] Fecal mercury concentrations, expressed per gram of dry weight, are roughly an order of magnitude higher in people who have an average of six to eight medium-sized amalgams than in individuals who are amalgam free.[90] Day-to-day variability in fecal mercury levels in amalgam bearers is remarkably low. Fecal mercury levels are highly correlated with the number of amalgams (Figure 23-1). Further, it has been demonstrated that fecal mercury levels decline significantly after extraction of amalgams.[91] Therefore, levels of fecal metals generally are more a representation of exposure to metals than an indication of total body retention. Current research efforts are focusing on the identification of metal complexing agents or phytonutrients that increase the biliary or fecal excretion of metals.

Fecal metals have been analyzed in autistic children (n = 54), and on average, metal levels were significantly higher compared with those in age-matched, nonautistic controls (n = 83).[84] The reason for the higher levels in association with autism is not known, and pica is a possible issue that may contribute to higher levels of exposure in autistic patients.

CONCLUSION

Long-term, low-level exposure to environmental toxins is a growing global problem, and evidence is accumulating to link the bioaccumulation of toxic metals in humans to subtle and overt health effects. Increasing numbers of patients dissatisfied with the care provided by clinicians who rely only on methods for the assessment of acute metal poisoning are seeking out progressive clinicians who are aware of the value of tools that are yet to be accepted for the assessment of subacute metal toxicity. Analyses of metals in hair, blood, and urine all have advantages and disadvantages, and no single test is likely to enable unequivocal diagnosis of "subclinical" metal toxicity. However, consideration of the results of the various tests discussed in this chapter as well as a complete medical examination, exposure history, and other findings can be used to design a comprehensive therapeutic detoxification program. Table 23-1 provides an overview of the value of the various tests for assessing a patient's potential problem with metals.

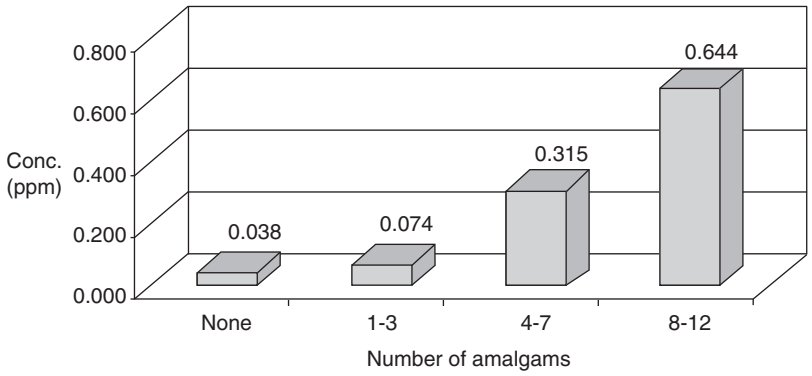

FIGURE 23-1 Fecal mercury levels versus the number of dental amalgams. Fecal mercury (microgram per kilogram dry weight) was plotted against number of amalgams for 200 subjects. (Data from Bass DA, Urek K, Quig D. Clin Chem 1999;45:A164. Poster presented at American Association of Clinical Chemistry Conference, Measurement of Mercury in Feces, New Orleans, July 1999.)

TABLE 23-1 **Summary of the Potential Value of Hair Analysis and Urinalysis**

		Urine (Retention)			
METAL/METALLOID	**HAIR (EXPOSURE)**	**NO PROVOCATION**	**DMSA**	**DMPS**	**CA-NA_2-EDTA**
Aluminum	Fair	Poor	Poor	Poor	Fair, best with deferoxamine
Antimony	Good	Poor	Good	Good	Good
Arsenic	Good	Poor	Good	Excellent	Poor
Cadmium	Fair	Poor	Fair	Fair	Excellent
Lead	Good	Poor	Good	Fair	Excellent
Inorganic mercury	Poor to fair	Poor	Excellent	Excellent	Poor
Organic mercury	Excellent	Poor	Excellent	Excellent	Poor
Nickel	Poor	Poor	Fair	Fair	Good
Tin	Poor	Poor	Good	Good	Good
Iron	Poor	Poor	Poor	Poor	Good, best with deferoxamine
Tungsten	?	Poor	Fair	Fair	Poor
Uranium	Good	Poor	Poor	Poor	?, Poor

Summary of the potential value of hair analysis (exposure), and the most commonly used provocation agents used in conjunction with urinalysis for the detection of retention of specific metals. It is emphasized that retention is not necessarily associated with overt toxicity. The qualitative guidelines are based on the author's perception of affinities (in vivo) derived from examination of thousands of test results, and stability constants as determined under highly defined conditions in vitro. The information provided does not include the potential use of adjunctive agents and/or protocols and does not cover all known metal complexing agents.

Ca-Na_2-EDTA, calcium-disodium ethylenediaminetetraacetic acid; DMSA, meso-2,3-dimercaptosuccinic acid; DMPS, Dimaval,-(R,S)-2,3-dimercapto-propane-1 sulfonate.

INTRODUCTION

Studies assessing the bioavailability of minerals in humans first appeared in the scientific literature in the 1960s,[1-3] and over the ensuing years it became clear that minerals play an important role in the biochemistry of the human body.[4,5] Abnormal levels of minerals can have deleterious effects on multiple enzyme systems, neuronal structures, and organs, including the brain, heart, thyroid, liver, kidneys, and skin.[4] Thus, mineral analysis can be an important health assessment tool for many patients. Opinions vary considerably as to which tissue or body fluid may be "best" for the assessment of any or all nutritional element(s).

In general, nutritional elements are better evaluated in blood or in urine. Blood mineral status can be assessed from an intracellular (e.g., potassium in erythrocytes, zinc in leukocytes) or extracellular (e.g., copper in serum) perspective, or overall in whole blood (total cellular components and serum). Levels of elements in serum will vary day-to-day depending on dietary intake. Many factors, such as specific protein carriers and the ionic charge of an element and its capacity to be in equilibrium, may affect the usefulness and reproducibility of a specific assay method and the appropriateness of a chosen tissue. The life span of the cellular components of blood is about 3 to 4 months, so any analysis using these cellular components must be interpreted with this time frame in mind; reported values will reflect exposure and absorption that occurred during that period.

When mineral analyses involve the cellular components of blood, the clinician must ensure that samples are spun down immediately after collection, thereby separating the cells from the serum. If whole blood is allowed to sit for an extended period or is shipped without such separation, some of the cellular components will break down, allowing their contained elements to disperse into the liquid component of the sample. Subsequent centrifugation will remove all of the liquid component, leaving the remaining intact cells to be analyzed for their elements. In that scenario, erroneously low levels of intracellular elements would be reported.

Although hair analysis (see Chapter 17) does have the benefit of convenience and low cost, interpretation is made difficult by the ease with which hair can be contaminated from external sources of exposure. With that proviso, hair analysis can accurately reflect exposure to, and absorption of, a limited number of elements (e.g., chromium) or deficiencies of others (e.g., copper). The most appropriate use of hair analysis appears to be in the assessment of toxic metal exposure but even then, its utility remains highly controversial ("an unproven practice" according to the American Medical Association).[6]

Most clinicians employ whole blood or urine analysis in the evaluation of mineral status since these fluids are the simplest and most economical to collect and transport. Whole blood requires no centrifugation and, like urine, requires no special treatment, other than collection and shipping in approved containers. Red blood cell (RBC) analysis might best be utilized in the assessment of elements that are more commonly represented intracellularly (e.g., iron, potassium). Reputable laboratories use current technology (e.g., induction-coupled plasma mass spectroscopy) operated by highly trained personnel to perform these tests and to produce accurate and precise results. Excellent reference range data are available to allow appropriate interpretation of analytic findings.

MINERALS AND DISEASE

Serum levels of various minerals have been implicated as clinical markers of disease.[4] Patients with cirrhosis have demonstrated low serum selenium,[7] calcium,[8] magnesium,[9] and zinc.[10] Those with emphysema and cancer have shown elevated serum copper concentrations; copper and manganese levels are often elevated in congestive heart failure, infection, and psychoses.[11] Other associations have been observed between trace minerals and breast cancer,[12] gastrointestinal malignancy,[13] and malignant ascites,[14] although in other studies, selenium, copper, zinc, and magnesium seemed to have no diagnostic value for distinguishing malignant from nonmalignant effusions[15] or cervical cancer.[16] Heart tissue levels of selenium, iron, copper, zinc, and phosphorus have been associated with ejection fraction and cardiac index.[17] In men infected with human immunodeficiency virus, helper T-type 4 cells seemed closely correlated with serum magnesium concentration.[18]

The ratios of trace elements may be indicators for various disease states. The concentrations of copper, zinc, and selenium, and their relative levels in whole blood and thyroid tissue, follow specific patterns for various thyroid disorders, including thyroid cancer. Further, and although the mechanisms are unclear, the copper-to-zinc ratio was found to be significantly increased in patients with breast cancer but not in patients with benign breast diseases.[19] In one study, serum copper-to-zinc ratios were shown to be of diagnostic and prognostic value in head, face, and neck cancer, with alterations in copper, zinc, and copper-to-zinc ratio related to the stage of the disease.[20] Other studies identified distinct differences in copper/zinc ratios among various levels of skin disease severity.[21]

ESSENTIAL MINERALS

There are a number of minerals that are common to all living organisms, in that they support biochemical processes in structural and functional roles. These essential elements are calcium, chloride, copper, iodine, iron, magnesium, manganese, molybdenum, phosphorus, potassium, selenium, sodium, and zinc (and perhaps, boron, cobalt, nickel, and sulfur). Other minerals, although not discussed here, have also been described as "essential," including chromium,[22] fluoride,[23] and vanadium.[24]

Calcium

Dietary sources of calcium include dairy products, canned fish with bones (e.g., salmon, sardines), green leafy vegetables, nuts, and seeds. Assessment of dietary intake of calcium is confounded by multiple factors that affect absorption, such as the quantity of fiber and other natural chelators in the diet; gastric acidity; the ratio of dietary calcium to phosphorus (and dietary magnesium); as well as gut transit time and other factors.

Serum calcium is so closely regulated (by the parathyroid gland) that its use as an indicator of calcium balance is not reliable when considered in isolation. Measurement of ionized calcium may be useful in evaluation of calcium status. Urinary calcium is of value in a patient with a known low total calcium intake and persistent calciuria. Hair calcium levels are subject to considerable variability and should not be taken as a quantitative determination of calcium status (although a relationship between hair calcium level and coronary disease has been reported).[25,26] In patients with high phosphorus and low calcium intakes, hair calcium level was consistently reported as much as three times higher than normal. Hair calcium returned to normal with proper supplementation and dietary changes.[27]

In one study that evaluated intracellular, plasma, and membranous levels of calcium and magnesium in hypertensive patients, there were no differences between controls and patients. However, the absolute levels of calcium and magnesium were lower, and the calcium/magnesium ratio in membranes was significantly higher in patients with essential hypertension than in healthy subjects.[28]

The best test to evaluate body calcium sufficiency may well be whole blood analysis, since this will assess calcium present in serum, intracellularly, and in the cell membranes.

Chloride

Chloride is necessary for the production of hydrochloric acid in the stomach and is also essential in cellular pump functions. The main dietary source of chloride is table salt. Chloride is readily assessed in serum and in urine.

Increased serum chloride may be associated with dehydration but could be present with either a metabolic acidosis or a respiratory alkalosis. High chloride can also be present along with elevated sodium in conditions such as Cushing disease. Urine chloride analysis, and often the analysis of urine sodium as well, may be important when considering alkalosis or acidosis or when assessing high or low serum chloride levels. Low serum chloride accompanies low serum sodium; low chloride may be associated with metabolic alkalosis and is often seen with prolonged emesis or in conditions causing respiratory acidosis, such as chronic obstructive pulmonary disease.

Body chloride levels are best evaluated in serum along with other electrolytes such as sodium. Urine chloride is a necessary component of a full electrolyte assessment and/or a metabolic panel.

Cobalt

Cobalt is essential in the production of vitamin $B_{12,}$ which is synthesized by bacteria. Cobalt metabolism and testing is better discussed elsewhere, especially in the context of vitamin B_{12} deficiency.

Copper

Under normal conditions, far more copper is absorbed than is needed by the body. Dietary sources include beans, eggs, fish, fresh fruits, liver, milk, mushrooms, nuts, oysters, peas, poultry, and whole grains. Nearly all dietary copper is stored initially in the liver, leaving only a small percentage in the blood. The principal mechanism for the control of copper homeostasis is excretion through the biliary system.

Because 95% of copper in serum is bound to the protein ceruloplasmin, there is almost no ionic copper so urinary copper output usually is minimal. At present, analysis of copper in serum may be the best indicator of body copper levels, provided that clinical conditions known to cause abnormal copper metabolism (e.g., Wilson's disease, cirrhosis of the liver) have been ruled out.[27] Some studies have shown hair copper measurement to be an acceptable method of assessing copper status[29,30] with the same provisos as mentioned previously regarding the ruling out of other illnesses known to affect copper metabolism and retention. When high copper levels are seen on hair analysis, external copper contamination (e.g., exposure to swimming pool and hot tub water, which are often disinfected with copper-containing chemicals) always should be considered.

Iodine

Iodine is necessary for the synthesis of thyroid hormones; iodine deficiency may lead to enlargement of the thyroid gland (goiter). Although iodine is readily measurable in urine, levels are highly variable[31]; thus, evaluation of urine iodine is not a reliable method to assess body iodine status. In contrast, it has been suggested that whole body sufficiency of iodine may be assessed in urine using an "iodine loading test."[32] Interpretation of the results of this test presupposes specific receptor/storage sites that take up and store iodine/iodide. When body storage of iodine/iodide is optimal, the percentage excretion of an oral loading dose of iodine/iodide excreted in urine is maximal; some authors purport that body stores are optimal when excretion is 90% or more.[33] An emerging assessment of iodine status is serum thyroglobulin, which appears to be a better measure of iodine status over weeks and months.[34]

Iron

Iron is essential for the function of many enzymes and has a role in the production of proteins (e.g., hemoglobin). Dietary sources include beans, dark green leafy vegetables, dates and figs, dried fruits, egg yolk, fish, molasses, nuts, organ meats, red meat, shellfish, as well as whole and enriched grains. Serum iron concentration has long been used as an indicator of iron deficiency. In practice it is not of much value when taken in isolation because there is considerable variation in serum iron levels, even when samples are taken from the same person at the same time each day. Serum iron measurement is much more reliable when combined with other indicators, such as serum transferrin or ferritin.

Ferritin is an iron storage protein accounting for 20% of the total body iron in normal adults. It is found principally in the cytoplasm of reticuloendothelial and liver cells, and, to some degree, in developing red cell precursors in bone marrow. This protein is involved in both absorption and recycling of iron and is a convenient and generally reliable indicator of total body iron stores.

A decrease in serum ferritin level (normal 12 to 300 ng/mL) is an early sign that body iron stores are low. As iron deficiency progresses, anemia (normal hemoglobin 13 to 15 g/100 mL), decreased serum iron concentration (normal 75 to 150 mcg/100 mL), and elevated iron-binding capacity (normal 300 to 400 mcg/100 mL) become apparent.[35,36] Serum ferritin may not be completely reliable in several common conditions, including cancer, infections, inflammation, and acute and chronic liver diseases, where it might be elevated. When iron overload is associated with hemochromatosis, hemosiderosis, or thalassemia, serum ferritin is also elevated.

The best way to evaluate body iron stores may well be with RBC analysis coupled with serum iron, serum ferritin, and total iron binding capacity.

Magnesium

Magnesium is essential for adenosine triphosphate (ATP) production and as a structural component of bones. Good dietary sources include nuts, soy beans, and cocoa mass. Measurement of magnesium status presents some difficulties, but the magnesium retention test is probably the most accurate, though cumbersome, method of assessment.[37] However, analysis of white blood cell magnesium content may be nearly as accurate as the magnesium retention test.[38]

Serum magnesium concentration may be influenced by many factors; it constitutes about only 1% to 3% of total body magnesium and does not reflect magnesium levels in other tissues.[39] The level of binding, complexing, or chelating of magnesium to serum proteins and other fractions is subject to many uncontrollable variables. Serum magnesium levels as low as 1.2 mEq/L have been measured in patients with normal total body magnesium.[40]

Erythrocyte membrane tests may also be useful in testing magnesium status (see previous discussion of calcium) and may be more clinically relevant than either plasma or intracellular studies.[19] Although the calcium/magnesium ratio in erythrocyte membranes was shown to be high in essential hypertension patients, it is unclear whether this finding is a cause or an effect of hypertension. However, it has been suggested that magnesium levels are low in hypertensive patients.[40]

The best test to evaluate body magnesium sufficiency may well be whole blood analysis since this will assess total magnesium in serum, intracellularly, and in the cell membranes of both red and white blood cells.

Manganese

Manganese is a trace element. It serves as a cofactor in enzyme functions (e.g., superoxide dismutase) and is essential in carbohydrate metabolism and production of skeletal and connective tissue development, and is a catalyst in fatty acid and cholesterol production. Dietary sources include dark green leafy vegetables, dried fruits, dried legumes, nuts, and whole grains. Assessment of body status for manganese is difficult as it is normally present in trace amounts (1% of the level of copper or zinc in blood).

Whole blood manganese concentration is a valid indicator of body manganese and soft tissue levels.[41] Proper technique is essential in the collection procedure as well as the actual analysis. Hair manganese level may be a rough indicator, especially in chronic toxicity, but whole blood manganese is the most reliable measurement tool.

Molybdenum

Dietary sources of molybdenum include beans, peas, red meats, and whole grains. It is a trace element important in xanthine, aldehyde, and sulfite oxidase (metabolism of sulfur-containing amino acids) systems. Xanthine oxidase catalyses oxidative hydroxylation of purines and pyridines; aldehyde oxidase oxidizes purines, pyrimidines, and pteridines and is involved in nicotinic acid metabolism. Sulfite oxidase deficiency or absence leads to neurologic symptoms and early death. Reduced dietary intake may result in low urinary molybdenum excretion, low serum uric acid, and excessive urinary xanthine excretion.[6] Molybdenum deficiency has been reported as occurring in in-born errors of metabolism and in patients receiving total parenteral nutrition.[42] Body sufficiency of molybdenum is best assessed by erythrocyte or whole blood analysis.

Nickel

Nickel is generally accepted as being a trace element in animals,[43] but its importance in humans requires further study.[44] Food sources of nickel are limited except perhaps in the case of high-acid prepared foods. It has been reported to be involved in iron metabolism and in stabilizing the structures of nucleic acids and proteins,[45] and it may be a cofactor of some enzymes.[46] Recent nickel exposure is best assessed by whole blood analysis. Nickel is rapidly

cleared by urinary excretion, so acute exposure to excessive nickel can be readily assessed by urine element analysis.

Phosphorus

Phosphorus serves a multiplicity of roles in human metabolism. Phosphorus is readily available in most foods, even in fast foods and especially in soft drinks. It is used as a structural component of bones (hydroxyapatite is a combination of ionic calcium and phosphorus). It is important in DNA, RNA, and energy production (ATP); in cell membrane structure (phophoslipids); and in most second messenger signaling pathways. It is involved in the renal production and serum concentration of 1,25-dihydroxy vitamin D.[47] High serum phosphorus is a predictable component of end-stage renal disease where no dietary restriction or other mitigating treatment is provided.[48] Intracellular phosphorus levels can be assessed with RBC analysis. Serum analysis provides an excellent evaluation of extracellular phosphorus levels, and whole blood element analysis provides a simple and straight forward method of assessing overall body phosphorus status.

Potassium

Potassium is an electrolyte and, along with sodium, essential to the regulation of ATP and the triggering of nerve and muscle activity. Dietary sources include bananas, legumes, potatoes (skins), and tomatoes. Consumption of a diet high in sodium (e.g., fast food items) can predispose to a potassium deficiency. Potassium is primarily an intracellular ion, and so serum measurements may not accurately reflect body stores. A low serum potassium level usually indicates an advanced intracellular deficit; however, an intracellular deficit may also occur with normal or high serum potassium concentrations.

RBC potassium content has been shown to mirror the potassium content of other tissue cells.[43,49] Although RBCs do not have nuclei, the sodium–potassium membrane pump that maintains the proper influx and efflux of these ions is intact. Whole blood potassium concentration is almost as accurate as the RBC potassium level because 98% of potassium is intracellular. The validity of intracellular potassium levels was demonstrated in a study where the electrocardiographic repolarization phase in elderly subjects was measured; alterations of repolarization correlated well with intracellular potassium levels but showed no correlation with serum levels.[50]

Selenium

Selenium is a trace element. Dietary sources of selenium include red meat, seafood, Brazil nuts, and whole grains. It is a cofactor essential to the activity of antioxidant enzymes such as glutathione peroxidase. Selenium may replace sulfur in cysteine to produce selenocysteine. Polypeptides containing selenocysteine include such selenoproteins as glutathione peroxidases and thioredoxin reductases (increases metallothionein redox capacity; supports vitamin E regeneration). Selenium deficiency may be associated with metal toxicity symptoms (due to lack of reduced metallothionein capacity).

After absorption, selenium is distributed throughout the tissues but does not seem to equilibrate with blood selenium levels. Blood selenium levels do not correlate with selenium intake, except at extremes.[51] Furthermore, serum levels of selenium do not appear to be associated with mortality and morbidity in relationship to infectious disease,[52] although one study found low serum levels of selenium and zinc to be associated with advanced gastrointestinal cancer.[6]

RBCs are high in glutathione peroxidase and could provide a means of assessing selenium levels, but may not give a good picture of total body status. Whole blood is generally the choice for assessment of selenium sufficiency.

Sodium

Sodium is an electrolyte and is essential, along with potassium, in the regulation of ATP. Sodium and chloride ions are the major electrolytes of the body. Dietary sources include table salt, sea vegetables (e.g., kelp, seaweed), milk, and spinach. Sodium and water depletion (e.g., dehydration, heat stroke, prolonged and excessive diarrhea or vomiting) can lead to hypotension; excessive long-term sodium intake (e.g., diets high in fast foods, prepared foods) is associated with hypertension. Sodium status is best assessed in serum.

Sulfur

Sulfur is essential for amino acid production and is obtained from cysteine and methionine contained in dietary protein sources. Sulfur sufficiency is best assessed with analysis of urine for essential elements. High urine sulfur may be seen in dehydration, recent use of thiol-containing complexing agents (e.g., dimercaptosuccinic acid, 2,3-dimercapto-1-propanesulfonic acid), high intake of sulfur-containing foods, and/or nutritional supplements (e.g., *N*-acetylcysteine, lipoic acid), and if there is impaired capacity to reabsorb cysteine (cystinuria). The possibility of cystinuria can be evaluated through urine amino acid analysis.

Zinc

Zinc is essential to the production and function of many enzymes, such as carboxypeptidase, alcohol dehydrogenase, and carbonic anhydrase. It is an intracellular ion, and some research shows that serum zinc concentrations are not sensitive indicators of depletion.[53] Urinary zinc level is also not a good indicator. Low hair zinc levels may indicate depletion, but normal values do not rule out low body stores.[24,54,55] Leukocyte zinc level has been investigated and found to be an accurate index of body stores.[56] In one investigation, 16 young women were given high and then low zinc dietary intake for specified periods. Low zinc intake status was not correlated with plasma zinc levels. Plasma zinc concentration was not significantly lower during the low dietary intake period than during the high dietary intake period. However, there was no significant change in fractional zinc absorption or urinary zinc excretion.[57]

The best test to evaluate body zinc sufficiency may well be whole blood analysis, since this will assess zinc present in serum, intracellularly, and in the cell membranes of both red and white blood cells.

CONCLUSION

The increasing availability of reliable laboratory methods for mineral analysis undoubtedly will better assist clinicians in evaluating disease status, progression, and prognosis as well in helping to make better treatment decisions. However, no analytic test is better than the laboratory performing it. Proper collection and analytic procedures must be used, and each step in the

preparation and processing of a sample must be carefully performed and monitored. In hair analysis, proper sample preparation and the use of ultrahigh purity digesting acid and distilled water are extremely important. In blood and urine analysis, collection tubes specially designed for the specific tissues being sampled and the minerals being collected must be used. Where analysis of cellular components of blood is involved, care must be taken to separate these components from serum without delay and definitely before transport.

Ultimately, it is the clinician's responsibility to verify the validity of an analytic procedure and to choose a reputable laboratory well known for its expertise, accuracy, and precision of its results. These steps will allow the clinician to confidently interpret and apply the results of any analysis. Finally, and most importantly, treat the patient, not the laboratory work!

It should be noted that many of the articles listed in the Reference section are reviews, and thus can serve as sources of additional information.

CHAPTER 25

Oral Manifestations of Nutritional Status

Michael T. Murray, ND

CHAPTER CONTENTS

Introduction, *206*
The Healthy Mouth, *206*
Abnormalities of the Oral Membranes, *206*

INTRODUCTION

The structures and lining of the oral cavity offer valuable and easily accessible information on the nutritional status of an individual. Lesions may indicate a nutrient deficiency or may be manifestations of gastrointestinal or other disease.[1] Because of the very rapid cell turnover of the oral mucosa, these lesions often may precede other manifestations of nutrient deficiency or systemic disease. Some typical lesions are mucosal ulceration, cheilosis, gingivitis, and glossitis. Between 5% and 10% of the people in the United States are deficient in one or more nutrients, so signs of nutritional deficiency are common.

THE HEALTHY MOUTH

The ventral surface of the healthy tongue is covered with a smooth, pink mucous membrane and lymphoid follicles. On the dorsal surface, the filiform, fungiform, and circumvallate papillae (which contain the organs of taste) produce a rough, grayish red appearance. The thick epithelial tufts of the filiform papillae give the tongue its characteristic grayish white coating, whereas the globular, pale red fungiform papillae give it a speckled pink appearance. Furrows are not characteristic of the healthy tongue.

The buccal mucosa has a grayish red color and may be crossed by fine grayish ridges where it touches the closed teeth.

Healthy gums have a light reddish appearance and cover the roots of the teeth completely.

The assessment of oral health, obviously, must include the health and status of the teeth. Patients should be asked about their dental history and encouraged to have regular dental checkups. Here are some key nutritional considerations for examination of the teeth[2]:

- Having fewer than 20 teeth as an adult is associated with a significantly reduced capacity to eat nutritious foods, such as salads, raw fruit and vegetables, nuts, and whole grain products. The same applies even to denture wearers.
- Bulimia may manifest as erosive tooth wear.
- Osteoporosis may manifest initially as changes in jaw structure and/or loose teeth.
- Presence of mercury amalgams may be associated with systemic disease, especially neurologic conditions.

ABNORMALITIES OF THE ORAL MEMBRANES

Table 25-1 summarizes the typical oral manifestations associated with a particular nutrient deficiency, and Table 25-2 summarizes common disorders associated with oral manifestations.[1-12]

In general, ulceration should be considered a nonspecific expression of a disease state. A search for the etiology will usually result in a specific therapy. Aphthous stomatitis is a common example of a mucosal ulceration and is discussed in detail in Chapter 146.

Similarly, cheilosis is a common expression for acquired nutrient deficiency. Gingivitis is associated with the classic signs of scurvy, but other nutrients have now been shown to play a role in gingival health; this subject is discussed in Chapter 199. Glossitis is associated with numerous vitamin deficiency states, each with a characteristic appearance.

TABLE 25-1 **Oral Signs of Nutrient Deficiency**

NUTRIENT	SIGNS OF ORAL DEFICIENCY
Vitamins	
Biotin	Geographic tongue, atrophy of lingual papillae
Folic acid	Gingivitis, glossitis with atrophy, or hypertrophy of filiform papillae, cheilosis
Niacin	Intraoral burning, canker sores, halitosis, glossitis, tongue swollen with red tip and sides, swollen red fungiform papillae, filiform papillae becoming inflamed and losing their epithelial tufts (giving the characteristic slick red appearance)
Pyridoxine	Intraoral burning, glossitis, mucosal ulcerations and erosions, cheilosis
Vitamin B_{12}	Intraoral burning, mucosal ulcerations and erosions, painful glossitis with a beefy red or fiery appearance, eventually resulting in an atrophic (smooth and shiny) tongue
Riboflavin	Soreness and intraoral burning, cheilosis, angular stomatitis, glossitis with a magenta tongue
Vitamin C	Sore and bleeding gums, deep blue-red color to gums, loose teeth, follicular hyperkeratosis
Vitamin D	Intraoral burning
Vitamin E	Glossitis
Minerals	
Calcium	Periodontal disease, tooth decay
Iron	Cheilosis, atrophic glossitis, gingivitis, candidiasis, intraoral burning or pain, mucosal ulcerations and erosions, pallor
Zinc	Cheilosis, atrophic glossitis, gingivitis, candidiasis, intraoral burning or pain, mucosal ulcerations and erosions, pallor

Data from references 1-12.

TABLE 25-2 **Common Disorders Associated with Oral Manifestations**

ORAL MANIFESTATION	DISORDER(S)
Cheilosis	Crohn's disease, acrodermatitis enteropathica, alcoholism, celiac disease, malabsorption syndrome
Gingivitis	Crohn's disease, anorexia nervosa, celiac disease, scurvy
Erythroplakia	Dysplasia or carcinoma
Glossitis	Crohn's disease, diabetes, alcoholism, celiac disease, malabsorption syndrome, pernicious anemia, iron-deficiency anemia, amyloidosis, carcinoid syndrome, cigarette smoking, anemia
Intraoral burning	Menopause, diabetes mellitus, esophageal reflux, Sjögren's syndrome
Leukoplakia	Chronic irritation, dysplasia, early invasive squamous cell carcinoma
Ulcerations, erosions	Crohn's disease, ulcerative colitis, celiac erosions disease, corticosteroid use, acrodermatitis enteropathica, anorexia nervosa, pernicious anemia, iron-deficient anemia, mercury poisoning, nicotine withdrawal

Data from references 2-12.

Like glossitis, intraoral burning represents a nonspecific expression of a possible nutrient deficiency or systemic disease.[3-5] Possible causes in addition to those listed in Table 25-2 are as follows:

- Xerostomia
- Dentures
- Deficiencies of iron, vitamin B_{12}, folic acid, vitamin B_6, and protein
- Steatorrhea
- Antibiotic use
- Changes in mucosal innervation
- Anxiety states

In people who do not wear dentures, nutritional disorders are the most common causative factors.[2]

Leukoplakia is any white lesion of the oral cavity that cannot be removed by rubbing the mucosal surface. Although lesions are usually only a sign of chronic irritation, 2% to 6% represent either dysplasia or early invasive squamous cell carcinoma.[4]

Erythroplakia is similar to leukoplakia, except that it has a definite erythematous component. This is a far more serious sign, with 90% of such lesions representing dysplasia or carcinoma.

INTRODUCTION

The earliest sign of vitamin A deficiency is a decrease in dark adaptation, or poor night vision. Serum retinol levels are not sensitive enough to reliably identify mild deficiency states. A dark adaptation test has the advantage of more reliably identifying marginal vitamin A deficiency; however, classic dark adaptation testing is a cumbersome and time-consuming process (usually taking 45 minutes or longer).

A rapid dark adaptation test (RDAT) was described by Thornton[1] and evaluated by Vinton and Russell.[2] This rapid (6 minutes) test has significant clinical utility. The basis for the test is the measurement of the time of the so-called Purkinje shift. This term refers to the shifting of peak retinal wavelength sensitivity from the red toward the blue end of the visual spectrum during the transition from day (cone-mediated) vision to night (rod-mediated) vision. When color vision is nonfunctional, this shift causes the intensity, not the color, of blue to appear brighter than red under dim lighting.

CLINICAL APPLICATION

Although dark adaptation testing has the advantage of being an in vivo test, and therefore directly related to function, it is somewhat less specific. Box 26-1 lists conditions that may give abnormal dark adaptation results with a normal vitamin A status.

PROCEDURE

Equipment and Supplies

- Lightproof room
- A standard darkroom light fixture fitted with a 7.5 W bulb and a neutral-density filter (allowing 1% transmittance). The bottom of the fixture is suspended 1.2 m above the work surface, so that the target brightness on the work area is approximately 0.0068 candela/m^2.
- Munsell color disks with matte finish: five white disks (N9.5/-), six blue disks (5PB5/10), and seven red disks (5R5/10) (available from Munsell Color and Macbeth Division, Baltimore, Md.)
- A nonreflective work surface
- A stopwatch
- A standard x-ray viewbox

Method

1. The procedure is explained to the subject.
2. The subject's vision is light-adapted by fixation on a standard x-ray viewbox for 1 minute at a distance of 0.5 meters. The x-ray viewbox is then turned off (the darkroom light remains on).
3. The subject is given all 18 disks mixed in random order, and the stopwatch is started.
4. The subject separates the white and then the blue disks as fast as possible. Under these controlled lighting conditions, the subject will not be able to recognize the colors, because the cones cannot distinguish color with the limited light available. The ability to separate the disks by brightness therefore depends on

BOX 26-1 Conditions Causing Abnormal Rapid Dark Adaptation Test Results in Subjects with Normal Levels of Vitamin A

- Zinc deficiency
- Cataract
- Retinitis pigmentosa
- Diabetic retinopathy
- Severe errors of refraction
- Miosis caused by pharmaceutical agents
- Tinted corrective lenses

the rods. Any disk mistakenly separated by the subject is returned to the original pile until 100% accuracy of sorting is achieved, at which point the stopwatch is stopped and the time is recorded as the result.

5. The first test performed by a subject should be redone to allow for learning and standardization.

Results

Vinton and Russell[2] reported the following results.

In subjects with normal vision, results are given according to age group:

- 20 to 39 years old: 3.03 ± 1.00 minutes
- 40 to 60 years old: 4.41 ± 0.83 minutes

Results in subjects who are vitamin A deficient average 7.63 ± 1.79 minutes.

INTERPRETATION

The RDAT time depends largely on the individual setting. However, the difference in the RDAT time between normal and vitamin A deficient individuals is significant, and therefore standardization is easily achieved. The normal values depend on the age of the subject, with older subjects having an increased RDAT time. An increased RDAT time may also indicate a zinc deficiency.

CHAPTER 27

Biomarkers for Stool Analysis

Andrea Girman, MD, MPH

INTRODUCTION

Gastrointestinal (GI) dysfunction is a remarkably common experience in the United States.[1] The popular media are saturated with advertisements promising to soothe a wide variety of complaints, including (but by no means limited to) constipation, indigestion, reflux, bloating, and cramping. Those seeking relief beyond that offered on their local pharmacy shelves are substantial in number: GI-related complaints account for a significant percentage of visits made to primary care providers' offices.[2] As a group, many GI diseases carry significant morbidity and mortality—and many are currently poorly treated or in some cases completely untreated.[3] Yet the burden of GI diseases goes beyond individual physical costs: one survey estimated that over 40 billion dollars are dedicated to addressing GI-related issues annually.[4] Given the substantive toll that GI-related illnesses place on patients and the health care system—and given that current treatment methods to address them may be less than effective—it must be asked: what options do clinicians have to fully support their patients?[5]

Laboratory diagnostics that assess the stool for insight into the state of health of the gut have existed for decades, yet the evolution of technology is such that more sensitive and specific tools now exist for easy clinical application. Biomarkers for stool analysis measure key physiologic aspects of the gut: digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G) (or DIG). This physiologic assessment of DIG mirrors functional status, and provides a critical noninvasive way to evaluate and clinically approach the patient with GI complaints (Figure 27-1). Assessed together, stool analysis biomarkers provide an effective means of capturing underlying physiologic disruption that manifests as disease: eliminating the need for costly diagnostic testing where unnecessary; highlighting those individuals specifically at risk for organic disease who require immediate specialty referral; and identifying the source of gut dysfunction to apply simple, cost-effective treatments.

OVERVIEW OF THE GASTROINTESTINAL TRACT

A popular adage expounds, "You are what you eat." Over the course of a lifetime, it is estimated that a well-nourished adult will consume between 25 and 50 tons of food.[6] Yet given that these macronutrients—fats, carbohydrates, and proteins—must ultimately be broken down, taken up, and assimilated, perhaps the more appropriate maxim is, "You are what you digest and absorb."

Once taken in, dietary foodstuffs undergo a series of complex digestive processes in this tube within a tube. The human gut has a massive absorptive surface area to capture macronutrients and micronutrients critical to optimal physiologic function, yet the impact of its processes are increasingly understood to go beyond traditionally defined roles of digestion and absorption. The mucosal surface of the GI tract is the primary interface with our external environment, and gut commensal microflora interaction with this mucosal surface is critical for differentiating self from nonself—a phenomenon known as "oral tolerance." In addition, more than 70% of the body's immune tissue sits within the gut, and is both closely interconnected to—and continuously interacting with—the largest concentration of nervous tissue outside of the central nervous system (CNS). These immunomodulatory and neuroendocrine functions give credence to clinical concern that gut dysfunction may be a root cause not only at the level of local digestive issues

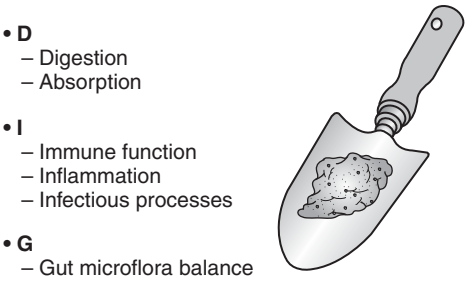

FIGURE 27-1 Key Physiologic and Functional Processes of the Gastrointestinal Tract: DIG

like constipation, gastroesophageal reflux disease, and irritable bowel syndrome (IBS), but also for many chronic, systemic illnesses like inflammatory bowel disease (IBD), Hashimoto thyroidits, systemic lupus erythematosus (SLE), rheumatoid arthritis, and migraine.

The following sections provide a broad-based overview of digestive physiology, followed by an in-depth look at key aspects of the gut utilizing the DIG framework—digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G)—and the biomarkers that provide insight into their function and/or dysfunction.

DIGESTIVE PHYSIOLOGY 101

Brain

As anyone watching a late-night food commercial may attest to, the process of digestion begins long before any food enters the mouth or stomach. The cephalic phase of digestion begins when anticipatory, visual, gustatory, and/or olfactory stimuli activate CNS centers, and result in parasympathetic stimulation of gastric activity.[7]

Mouth

Homogenization of ingested food first occurs in the mouth via the grinding and mixing action of the teeth. Salivary glands provide hydration to form a bolus and protect the pharyngeal and esophageal mucosa, primarily with secretory immunoglobulin-A (IgA) antibodies. The process of starch and fat hydrolysis is initiated with the release of lingual lipase, salivary amylase, and ptyalin.[8,9]

Esophagus

As the food bolus is swallowed, the epiglottis closes, providing a one-way valve that allows the food to pass into the GI tract and not the respiratory tract. Food is then transported down the esophagus in peristaltic waves past the lower esophageal sphincter into the stomach.

Stomach

The stomach produces churning action, and initiates protein and lipid hydrolysis. Peptides, amino acids, and fatty acids released in this process synchronize the release of pancreatic juice and bile into the small intestine.[8] About 2 L of gastric juice are produced each day, containing several important components.[10] Hydrochloric acid (secreted by the parietal cells) activates pepsinogen to convert to pepsin, which renders some minerals (e.g., calcium and iron) more absorbable. It also creates an essentially sterile environment to prevent bacterial overgrowth. Mucus forms an acid- and pepsin-resistant coating for the stomach lining. Gastric lipase secreted by gastric mucosa begins to hydrolyze triglycerols, producing 1,2-diacylglycerols and fatty acids. The optimal pH of gastric lipase is about 4, but the enzyme is active up to pH 6 or 6.5.[11]

Liver and Biliary System

The liver is the largest gland in the body, and performs an extraordinary number of tasks that impact every system of the body. Although the liver has critical vascular and metabolic functions, its secretory and excretory functions—especially as related to the synthesis and secretion of bile acids—are those that most directly impact digestion.

Because the by-products of lipid digestion have limited ability to dissolve in water, they have difficulty reaching the epithelial surface of the small intestine, which is covered by the unstirred water layer. To be more effectively absorbed, they must form aggregates (micelles) with bile acids (which act as biologic detergents) that can penetrate the unstirred water layer. Without bile acids, only a small number of lipid molecules permeate through the water layer to be taken up by the brush-border membrane of the enterocytes. Finally, fat soluble antioxidants (vitamins A, D, E, and K, as well as lutein and lycopene) also require bile acids for optimal absorption and utilization.

Pancreas

The pancreas plays a vital role in supporting the ongoing breakdown of the semi-fluid mass of partially digested food that flows from the stomach to the small intestine (chyme). Pancreatic duct cells secrete bicarbonate, which is critical for rapidly neutralizing gastric acid to preclude damage to the duodenal mucosa. In addition, pancreatic exocrine function results in the secretion of proteases, amylases, and lipases that further breakdown macronutrients (proteins, carbohydrates, and lipids) so that their components are readily absorbed across the intestinal mucosa.

Primary pancreatic exocrine insufficiency results from organic diseases of the pancreas (e.g., chronic pancreatitis, cystic fibrosis, severe acute necrotizing pancreatitis, pancreatic cancer). Secondary pancreatic exocrine insufficiency results from extra-pancreatic diseases such as celiac disease and Crohn's disease, GI and pancreatic surgical resection, as well as any condition that results in a compromise or blunting of the small intestinal brush border. These include inflammatory processes, infectious agents, food allergies, and dysbiosis and/or small bowel bacterial overgrowth. Whether of primary or secondary etiology, any compromise of pancreatic exocrine function can result in significant malnutrition related morbidity and mortality.[12]

Small Intestine

Most digestion and assimilation occur in the small intestine. Digestion is mediated chiefly by pancreatic enzymes, including proteolytic enzymes, nucleolytic enzymes, lipases, α-amylase, and phospholipase A_2, which hydrolyze macromolecules to oligomers, dimers, or monomers.[8] Pancreatic enzymes are most active in the neutral pH range,[10,13] and bicarbonate begins the process of neutralizing stomach acid. Pancreatic proteases are secreted into the duodenum as inactive precursors, trypsinogen,

chymotrypsinogen, and proelastase, and are activated by brush-border enzymes, such as enterokinase, to form trypsin, chymotrypsin, and elastase, respectively.[10]

The digestive and absorption capacities of the small intestine are greatly enhanced by circular folds and fingerlike projections of the intestinal mucosa called microvilli. This region, dubbed the "brush border," increases the luminal surface area of the intestinal wall by about 600 times, creating a total absorptive surface of approximately 200 to 250 m^2, essentially the size of a tennis court.[10,13,14]

Even after prolonged contact with pancreatic enzymes, a substantial portion of ingested carbohydrates and amino acids depend on hydrolytic enzymes (disaccharidases such as maltase, sucrase, lactase, enterokinase, and peptidases) produced by the brush-border membrane to complete their digestion.[10]

For this reason, damage to the intestinal brush border—resulting from inflammation, trauma, parasitic infection, bacterial overgrowth, long-term nonsteroidal anti-inflammatory drug use, and other factors—may interfere significantly with the proper absorption of nutrients. Such damage also can disrupt the intracellular tight junctions that are vital to the protective barrier function of the gut mucosal layer, increasing the intestinal permeability of potentially harmful macromolecules, such as bacteria and toxins, into the systemic circulation. This state of increased intestinal permeability, sometimes referred to as "leaky gut," has been cited as a potential contributory or causative factor in gluten enteropathy, Crohn's disease, food allergy, various arthritides and autoimmune diseases, chemotherapy complications, and a variety of other clinical conditions.[15-19]

Large Intestine

A primary role of the large intestine is to absorb water, about 1 L/day. The large intestine also provides an environment for microbial fermentation of soluble fiber, starch, and undigested carbohydrates. Soluble fibers are more readily fermented than insoluble fibers.[20]

Nondigestible carbohydrates (e.g., fiber), polysaccharides, and oligosaccharides contain chemical bonds that make them incapable of complete digestion by pancreatic or brush-border enzymes. As they move through the digestive tract, these undigested compounds play an important role in intestinal transport mechanisms. Once in the colon, they are cleaved and modified by enzymes produced by resident colonic bacteria to form short-chain fatty acids (SCFAs) and various gases, such as methane, hydrogen, and carbon dioxide.[11]

ASSESSING GASTROINTESTINAL HEALTH: DIG

As noted previously, a clinical approach to evaluating the functional state of gut health can be one that is based on the primary physiologic roles of the gut. This approach is captured by the mnemonic DIG: digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G).

DIGESTION/ABSORPTION

Digestive Dysfunction

The first step in optimizing GI health is optimizing digestive function. Because numerous organs are involved in the digestive process, maldigestion can occur with malfunction at any level of digestive physiology, resulting in both local and systemic signs and symptoms. Maldigestion may result from an inadequate cephalic phase, leading to inadequate secretion of salivary amylases and proteases; insufficient mastication; hypochlorhydria; pancreatic insufficiency; bile insufficiency; small intestinal villous atrophy; and brush-border enzyme destruction.

As an example, hypochlorhydria has been hypothesized to be the root cause of a number of clinical conditions, including reduced mineral and amino acid absorption, depression, and other syndromes.[21,22]

In addition, interest has been expressed in the medical literature about the connection between the robust use of pharmaceuticals promoting gastric acid blockade and chronic clinical complaints. Research indicates that small bowel bacteria overgrowth, and associated disorders such as blunting of brush-border enzyme activity and decreased pancreatic exocrine function, may be an iatrogenic consequence of overprescribing of proton pump inhibitors.[23-25] Given that long-term use of drugs that markedly reduce gastric acid secretion may negatively affect dietary and nutriceutical calcium absorption, concern has also been raised about their potential to increase the risk of fracture in individuals with osteoporosis, although the greatest potential for this may be in patients already at risk for loss of bone mineral density.[26-29]

Maldigestion associated with pancreatic exocrine insufficiency results in an inadequate delivery of enzymes to the small intestine, and can lead to inadequate breakdown of fats, carbohydrates, or protein. The net effect is poor nutrition and an unhealthy environment for the flora of the large intestine. Significant decreases in exocrine pancreatic secretion have been associated with the aging process,[30] and clinically, may be associated with osteoporosis[31,32] and diabetes.[33-35]

Absorptive Dysfunction

Malabsorption can be characterized by abnormal fecal excretion of fat (steatorrhea); abdominal pain; and variable malabsorption of fats, fat-soluble vitamins, other vitamins, proteins, carbohydrates, minerals, and water. Common causes include:

- Maldigestion
- Hypochlorhydria
- Small bowel bacterial overgrowth
- Deficient bile production, resulting in inadequate solubility of fatty acids[11]
- Chronic inflammation of the small intestine
- Rapid transit, which does not allow adequate time for absorption

Malabsorption often increases with age[36]: atrophic gastritis is estimated to affect 10% to 30% of individuals more than 50 years old and often leads to inadequate absorption of key nutrients such as vitamin B_{12}.[37]

General malabsorption syndromes are associated with many disorders of the intestinal tract, including celiac disease, gluten enteropathy, IBD, infectious processes such as giardiasis and cryptosporidiosis, lactose intolerance, and eosinophilic gastroenteritis. Because amino acids, carbohydrates, vitamins, and minerals are absorbed through different processes, individuals with malabsorption are at risk for development of a wide range of nutrient deficiencies.

Biomarkers for Digestion/Absorption

Pancreatic Elastase 1

Pancreatic elastase 1 (PE1) is a proteolytic enzyme secreted exclusively by the human pancreas, and as such, reflects overall pancreatic exocrine function.[38] It is an extremely stable, reliable, and specific marker,[39] and correlates well with gold-standard,

stimulated pancreatic function tests.[40] PE1 is concentrated five- to six-fold higher in feces than when it enters the duodenum, reflecting an overall stability of this biomarker in the GI tract.[41] It is not degraded during intestinal transit, and is generally not affected by increases or decreases in intestinal transit time,[42] although its sensitivity may be diminished in cases of liquid diarrhea.[43] Unlike other pancreatic markers, such as chymotrypsin, PE1 results are not affected by pancreatic enzyme replacement therapy,[39,40] a feature that makes it a valuable marker for monitoring and adjusting exogenous enzyme replacement.[39]

PE1 appears to have less sensitivity when diagnosing mild exocrine pancreatic insufficiency, and may have limited use in differentiating pancreatic from nonpancreatic steatorrhea or diarrhea.[44]

Although research typically indicate levels of PE1 less than 200 mcg/g to be consistent with normal pancreatic exocrine function, healthy individuals produce on average 500 mcg/g of PE1. Given that, PE1 levels greater than 200 mcg/g and less than 500 mcg/g suggest a deviation from optimal pancreatic function. PE1 values between 100 and 200 mcg/g suggest moderate pancreatic insufficiency, and values less than 100 mcg/g are considered to be consistent with severe pancreatic insufficiency.[45,46] Enzymatic support of pancreatic insufficiency is warranted, and strength of supplementation–typically based on the level of lipase units–should be modulated based on the degree of pancreatic insufficiency indicated by the PE1 level (Table 27-1).

Reduced PE1 has been reported clinically in patients with type 1 and type 2 diabetes.[47,48] chronic pancreatitis,[49,50] osteoporosis,[32] cystic fibrosis,[51] trauma states,[47] and in intestinal malabsorption states associated with mucosal atrophy such as celiac disease.[52,52a]

Putrefactive Short-Chain Fatty Acids

Valerate, isovalerate, and isobutyrate are produced exclusively by bacterial fermentation of proteinaceous material (polypeptides and amino acids). These SCFAs are putrefactive, and their presence suggests underlying maldigestion and/or malabsorption from dysfunctional states such as hypochlorhydria or exocrine pancreatic insufficiency,[53] or bacterial overgrowth in the small intestine. Other causes are GI disease (resulting from the fermentation of blood or mucosal cells delivered to the colon)[54] and rapid transit time (resulting from inadequate time for digestion and absorption of peptides and amino acids).[55]

Fecal Fats

Fecal fats include triglycerides, long chain fatty acids, cholesterol, and phospholipids, and are derived primarily from the dietary ingestion of fat. Elevated levels of fecal fats in the stool suggest fat malabsorption (steatorrhea), which can occur as a result maldigestion and/or impaired uptake of fatty acids. In addition, any condition that results in impairment of lipase activity and bile acid production and release may result in fat malabsorption. These include pancreatic insufficiency, cholestatsis, short bowel syndrome, and celiac disease.[56]

TABLE 27-1 **Pancreatic Elastase 1 Levels, Degree of Pancreatic Insufficiency, and Enzyme Supplementation**

>500 mcg/g	Optimal
351-500 mcg/g	Normal, but not optimal
201-350 mcg/g	Mild insufficiency
101-200 mcg/g	Moderate insufficiency
<100 mcg/g	Severe insufficiency

IMMUNOLOGY/INFLAMMATION/INFECTIOUS PROCESSES

As noted previously, more than 70% of the body's immune tissue sits within the GI tract.[57] This immune tissue has a complex and dynamic relationship with the commensal microflora that colonize its surface—the primary interface with an external environment rich in both supportive dietary antigens as well as pathogenic agents. The gut commensal microflora exist in this macronutrient dense intestinal environment, and are significant contributors to the process of digestion, building of essential nutrients, and holding nonbeneficial bacterial counts in check. How is it then that host immune function is modulated to allow for the acceptance of self (as well as supportive commensal organisms and dietary antigens), even as it is vigilantly surveying for and combating against pathogenic microorganisms?

The answer appears to lay with an exquisitely balanced, ongoing inflammatory response by the intestinal immune system: it is capable of mounting strong inflammatory responses against pathogenic agents while concomitantly providing inhibitory signals that preclude responses against commensal bacteria.[58,59] Any alteration of this equilibrium, for example, as a result of gut microflora imbalance, genetic predisposition, or immune dysregulation, will result in an upregulation of the gut inflammatory response. Diagnostically, this may be reflected by the release of the biomarker calprotectin from neutrophils.[60] Clinically, the breakdown of this intestinal immune balance has been implicated in the development of diseases marked by significant inflammation, such as IBD,[61-63] and has been postulated to play a role in the development of extraintestinal allergic and autoimmune disorders.[64] Microflora imbalance has also been reported in patients with IBS.[65]

Biomarkers for Immune Function/Inflammation/Infectious Processes

Eosinophil Protein X

Eosinophil protein X (EPX) is a basic cellular protein with potent cytotoxic and neurotoxic properties, and is a marker of eosinophil activation and degranulation. Mobilization of eosinophils in the gut appears to occur in response to immune-mediated inflammatory responses.[66,67]

Clinically, fecal elevations of EPX have been described in IBD, IgE-mediated food allergy, parasitic infections, and collagenous colitis.[68-79]

Calprotectin

Calprotectin belongs to a group of calcium-binding neutrophil-derived proteins. Because neutrophils are typically mobilized in response to increased mucosal permeability, cell or tissue damage, and infectious processes, elevations in calprotectin may be seen in the presence of inflammatory, neoplastic, and/or infectious disease processes.[80,81]

Clinical application of this biomarker has been directed toward discerning the best approach for the patient with functional abdominal symptomology. Specifically, calprotectin has been evaluated (in conjunction with Rome criteria) as a diagnostic biomarker to distinguish between IBS and IBD.[82-84] Surveys indicated that up to 12% of primary care visits were comprised of IBS-related complaints and accounted for 28% of referrals to gastroenterologists.[85,86] Because

symptoms often overlap, early IBD may be inappropriately labeled as IBS. At least one study reported that more than 25% of patients with Crohn's disease had been misdiagnosed as having IBS in the prodromal stages of their disease.[87] Attempts to define organic disease in patients with IBS inevitably results in the application of more invasive diagnostic imaging procedures and escalated health care costs.[5]

Calprotectin has been found to correlate closely with IBD activity[88] and provides a highly sensitive, specific, and noninvasive alternative for assessing inflammatory activity in IBD.[84,89] Fecal calprotectin levels have been shown to correlate significantly with histologic and endoscopic assessment of disease activity in ulcerative colitis[90] and with indium-111–labeled white blood cells (the gold standard for assessing gut inflammation) in patients with Crohn's disease.[91] In one report, more than 95% of patients with IBD had elevated fecal calprotectin levels.[92]

Calprotectin has been used to predict relapse in patients with established IBD and to evaluate the effectiveness of therapeutic regimens as well.[68,93,94]

Because severity of inflammation is indicated by varying levels of calprotectin, treatment options and urgency of diagnostic intervention vary as well (see Table 27-2).

Infectious Agents

Helicobacter pylori. *Helicobacter pylori* remains a prevalent worldwide infection, with infection rates in middle-aged adults reaching more than 80% in areas of low socioeconomic status and 20% to 50% in most industrialized countries.[95] *H. pylori* continues to be a causal link for the development of peptic ulcer disease (an estimated 10% to 20% lifetime risk in infected individuals),[96] as well as a variety of other GI concerns ranging in severity from dyspepsia to gastric malignancy.[97,98]

Several diagnostic options exist in assessing possible *H. pylori* infection. Although histologic confirmation remains the gold standard, noninvasive measures such as urea breath testing, *H. pylori* stool antigen (HpSA) testing, and *H. pylori* polymerase chain reaction (PCR) are currently available.

HpSA diagnostics have been approved by the U.S. Food and Drug Administration for the detection of *H. pylori* pre- and posteradication therapy. This biomarker indicates the presence of *H. pylori* antigens shed directly into the stool, and provides increased ease of clinical use as well as diagnostic performance characteristics comparable to urea breath testing in both adult and pediatric populations.[99,100] It has been shown to accurately indicate treatment failure at 7 days after completion of eradication therapy (compared with 4 weeks for urea breath testing),[100-102] an important consideration for directing additional clinical intervention in patients who remain symptomatic or develop recurrent symptoms posttherapy.

Although PCR testing for *H. pylori* is currently offered as a noninvasive diagnostic alternative to endoscopy and biopsy as well, concerns have been raised about the high degree of false-positive results with this methodology.[103,104]

Clostridium difficile. *Clostridium difficile* is an anaerobic, spore-forming, gram-positive bacterium that can be part of the normal intestinal flora. Although typically considered an opportunistic infection occurring after antibiotic therapy, the epidemiology of *C. difficile* infection has shifted significantly. Its incidence has increased dramatically worldwide in the past decade, and new at-risk populations include individuals with community-acquired infection and no previous exposure to antibiotics, children, and pregnant women.[105]

C. difficile produces two toxins, A and B, which are its main virulence factors, and human infection can take many forms. These range from asymptomatic carrier states[106] and recurrent mild-to-moderate IBS-like manifestations, to severe symptoms indistinguishable from colitis (cramping, diarrhea, urgency, mucus, and blood) that may result in a misdiagnosis of IBD.[107]

Parasitic Agents

Research suggests that parasitic organisms may also act as etiologic agents of gut inflammation and dysfunction, including abdominal pain, diarrhea, and constipation.[108] One study found *Blastocystis hominis* to be present four times more frequently in IBS patients compared with control subjects. In addition, symptoms resolved in 80% of subjects with IBS when *B. hominis* was treated.[109]

Other parasitic agents identified by stool analysis that have been isolated from patients with clinical symptomology include *Dientamoeba fragilis*, *Entamoeba spp.*, *Endolimax nana*, and *Giardia lamblia.*[110-112] A recent review by an American diagnostic laboratory routinely surveying stool for parasitic agents found that 23.5% of nearly 14,000 clinical samples meeting *International Classification of Diseases 9th Edition* criteria for IBS tested positive for the presence of at least one parasite.[113] *B. hominis* was the most commonly identified organism (12.5% of positive samples), followed by *D. fragilis* (3.8%), *Entamoeba* spp. (3.4%), *E. nana* (2.2%), and *G. lamblia* (0.7%). Similar results have been reported by laboratories outside of the United States as well.[114]

TABLE 27-2 **Calprotectin Levels, Inflammation Severity Clinical Intervention**

<50 mcg/g	No inflammation
50-120 mcg/g	Mild inflammation
• Evaluate for dybiosis, allergies, infection	
120-250 mcg/g	Moderate inflammation
• Evaluate aggressively for source of inflammation	
>250 mcg/g	Severe inflammation
• Refer for diagnostic imaging (i.e., colonoscopy)	
• Begin treatment in patients with IBD. Therapy should persist until biomarker indicates that inflammation has resolved and mucosal healing has occurred.	

GUT MICROFLORA BALANCE

At birth, the human GI tract is sterile. Bacterial colonization begins within days of delivery, and evolves continuously over the first 1 to 2 years of life.[115] Early gut microflora development is impacted by a variety of factors: location and type of birthing, breast-feeding versus formula-feeding, and antibiotic use in infancy and childhood.[116-119] *Bifidobacteria* are typically the first organisms to populate the newborn gut, and research suggests that any event that results in inadequate gut colonization during early life may lead to an increased risk of infectious, allergic, and autoimmune disorders later in life.[120] Once established, the bacterial composition of the gut tends to remain relatively constant over the lifetime of an adult,[121] although environmental (pharmaceuticals, toxins, infectious agents), lifestyle (stress), and dietary (glycemic load, fiber content, essential fatty acid composition, macronutrient/micronutrient composition, and pH balance) factors may induce shifts in commensal flora balance.[122,123]

Bacteria are present at every level of the GI tract and can be found in increasing density as one progresses from the upper gut (esophagus and stomach 10^3 to 10^5 organisms/mL luminal content) to the lower gut (large intestine 10^{10} to 10^{12} organisms/mL luminal content; feces 10^9 to 10^{11} organisms/mL luminal content). In addition, the human gut hosts a massive diversity of microflora species—more than 400 have been described to date. Anaerobic species comprise the vast majority of the microbiome in healthy individuals: these include obligate anaerobes such as *Bacteroides*, *Bifidobacterium*, *Lactobacillus,* and *Clostridium*, as well as facultative anaerobes such as *Escherichia coli*, *Citrobacter*, *Enterobacter*, *Proteus,* and *Klebsiella*.[124] At counts of greater than 100 trillion bacteria colonizing the GI tract, these nonhuman cells vastly outnumber the total number of human cells in the body. With a metabolic capacity greater than the liver—and accounting for roughly 3 lbs of body mass—this dynamic population of organisms could be considered a hidden organ in its own right.[125]

As noted previously, the bacteria that inhabit the human GI tract play a significant role in metabolic processes in the body. These include fermentation, SCFA and undigested dietary fiber metabolism, primary bile acid deconjugation, vitamin synthesis, and energy production. In addition, they are key immunomodulators, exert trophic effects on intestinal epithelia, and are a critical defense against pathogens—not only by competing for nutrients, space, and adherence intraluminally, but also by producing bacteriocidal substances.[126] For this reason, alterations in gut microbial balance (dysbiosis) may result in health-related consequences at both intestinal and extra-intestinal levels.[65,127-129]

In dysbiosis, organisms of typically low intrinsic virulence, including bacteria, yeasts, and protozoa, may grow or migrate beyond their normal limitations. This can result in intensified microbial competition for nutrients, damage to the gut mucosal layer, and alterations of host immune function,[130] and as a consequence, may increase the risk for nutritional deficiencies, inflammation, autoimmune disorders, and neoplasia.[126,131-135]

Given the potential for disease that results from altered host-flora dynamics, restoration of balance as a means of restoring health has been a fundamental tenet of natural medicine and an increasing area of research in traditional medical spheres. However, the question should be asked: what defines optimal gut ecology?

Analysis of stool samples has been historically used to provide insight into the microbial composition of the gut. Specifically, levels of growth on plated culture media can be quantified and reflect the density of bacteria in the distal colon. Studies comparing electron microscopic evaluation of the microflora with fecal culture suggest that 50% to 80% of total microscopic composition is recovered with stool culture methodologies. Limitations presented with the utilization of culture techniques include selectivity of growth based on media used and challenges posed by recovering strict anaerobes in a standard culture environment. Despite these limitations, use of molecular probes suggests that there is good agreement on the degree of biodiversity when fecal culture is compared with 16S rDNA sequence analysis. In addition, biomarkers that reflect the metabolic activity of the GI microflora provide insight into the optimal functioning of the microbiome.[136]

With the advent of the Human Microbiome Project, increased focus has been placed on use of molecular probe technology to characterize the microbial populations of the human body.

Given ongoing evidence linking the GI microflora, health, and disease, these research initiatives have sought to identify a core gut microbiome. A limited number of common species have been demonstrated in the human intestinal microbiota to date and indicate the promise of applying molecular probe techniques in defining beneficial bacterial composition. Given that research consistently demonstrates significant interindividual diversity and high intraindividual specificity, variability of microflora composition between individuals appears to be the norm, especially with aging.[137,138] In addition, although molecular probes have the capability of identifying the vast pool of species inhabiting the human gut, questions have been raised about the clinical relevance of such identification, as was noted previously with *H. pylori* PCR versus stool antigen testing. This is of particular concern when parasitic and/or pathogenic organisms are identified, because probe technology does not currently have the capacity to differentiate between the DNA of living organisms (active infection) and DNA fragments indicative of past infectious processes or incidental exposure.

Ultimately, characterization of the microflora is undertaken to correct imbalances that may be contributing to acute or chronic states of illness. Supportive therapies such as prebiotics and probiotics (see Chapters 115 and 116 on Prebiotics and Probiotics) are standard clinical tools for optimizing gut health, and supplementation has been shown to be of benefit in an array of medical conditions, including atopic dermatitis[124,139]; acute infectious and antibiotic-associated diarrhea[140-142]; cancer prevention[133]; IBS[143,144]; prevention of necrotizing enterocolitis[145]; prevention and treatment of pouchitis[146]; and ulcerative colitis.[147-149,150]

Although evidence exists that demonstrates clinical benefit, there is little consensus regarding what constitutes the most optimal therapeutic strain(s), concentrations, or timeline of treatment. With the emergence of molecular technology, there may be a point in the near future that allows individual targeting of probiotic therapies. Until that time, phenotypic markers that provide insight into the health of the microbiome—biomarkers reflecting digestion/absorption (D), immunology/inflammation/infectious processes (I), and gut microflora balance (G)—may be utilized to identify and monitor patients needing support.

BIOMARKERS FOR GASTROINTESTINAL MICROFLORA BALANCE AND METABOLIC FUNCTION

Beneficial Bacteria

Bifidobacterium, Lactobacillus, and nonpathogenic *E. coli* are the predominant strains of beneficial flora,[117] with the obligate anaerobic *Bifidobacteria* constituting about one fourth of the microbial flora found in adults.[151] In the distal colon, *Bifidobacteria* outnumber *Lactobacilli* by 1000:1.[152] Given that, quantification of *Bifidobacteria* via stool culture typically demonstrates recovery in the 3+ or 4+ ranges in a healthy microbial milieu. The facultative aerobe *Lactobacilli* and nonpathogenic *E. coli* are both typically recovered in the 1+ or 2+ ranges.[153]

Adequate amounts of *Bifidobacterium, Lactobacillus,* and nonpathogenic *E. coli* are essential for the maintenance of optimal digestive functioning, and as such, these species are utilized in culture diagnostics as indicators of gut microflora health. Recovery of their numbers in less than optimal ranges suggests alterations in gut microbial balance, and indicates a clinical need to ascertain the underlying etiology of the disruption, and ultimately, to assess the need for therapeutic support. The composition and distribution of the GI flora are impacted by a variety of factors as noted previously, including dietary intake, infectious agents, pharmaceuticals, and age. Stress also exerts a profound impact on gut flora and physiology, including increasing intestinal permeability, increasing bacterial adherence, and decreasing intraluminal levels of *Lactobacilli*.[123]

FIGURE 27-2 Probiotic recommendations by disease. From Isolauri E, Kirijavainen PV, Salminen S. Probiotics: a role in the treatment of intestinal infection and inflammation? Gut 2002 50: iii54-iii59http://gut.bmj.com/content/50/suppl_3/iii54.full.pdf.) Used with permission from BMJ Publishing Ltd.

Restoration of balance and improvement of clinical symptoms may be achieved by probiotic supplementation. As indicated in the peer-reviewed literature, increasing levels of probiotic support may be required with increasing levels of disease state severity (see Figure 27-2).[154]

Additional Bacteria

Bacterial cultures are capable of identifying any number of additional organisms present in the individual human gut. These organisms may or may not exert a pathogenic effect depending on the state of balance or imbalance of the gut microbial milieu in toto. Putting it another way: sometimes these agents are the source of gut dysfunction, and sometimes their presence is merely a reflection of underlying gut dysfunction.

Overgrowth of additional bacteria may cause clinical and subclinical malabsorption and increase bowel permeability to large molecules. Abnormalities of the immune or mechanical barriers can lead to enhanced uptake of inflammatory luminal macromolecules and pathogenic bacteria. Bacterial antigens are capable of inducing antibodies, which cross react with host antibodies, forming systemic immune complexes.[155,156] This process has been implicated in the etiology of chronic gut inflammation, as well as SLE and other connective tissue diseases.[157,158]

Bacterial species such as *Klebsiella* and *Proteus* are not routinely surveyed as components of standard microbiological assessments, but both have demonstrated antigenic cross reactivity to human leukocyte antigens (HLAs). *Klebsiella* has been associated with ankylosing spondylitis when cross reactivity occurs with the HLA-B27 antigen. Similarly, *Proteus mirabilis* has been associated with rheumatoid arthritis and is known to cross react with the HLA-DR4 antigen.[159,160]

Mycology

The GI tract in healthy individuals normally harbors small amounts of yeast. However, colonic yeast infections have attracted attention and controversy as a possible cause of chronic complex illnesses.[161] Investigators have hypothesized that *Candida albicans* may be involved in the etiology of allergic disorders such as scleroderma and asthma,[131,162] chronic fatigue,[163] chemical sensitivity,[161] and IBD.[164]

Biomarkers for Microflora Metabolic Activity

As mentioned previously, biomarkers that reflect the metabolic activity of the GI microflora can provide an adjunctive assessment of the microbial status of the gut. Diagnostic assays utilized include those that evaluate SCFAs, β-glucuronidase, and bile acid metabolism.[140]

Beneficial Short-Chain Fatty Acids

SCFAs are produced by the anaerobic bacterial fermentation of primarily nonabsorbed dietary fiber.[165] The rate and amount of SCFA production depends on the composition and density of microflora present in the colon, the substrate source, and GI transit time.[166]

There are three primary beneficial SCFAs—acetate, n-butyrate, and propionate—yet most clinical and research emphasis has been placed on n-butyrate. Butyrate plays a major role in the physiology of the colonic mucosa and serves as the major energy source for the colonocyte.[167] In addition, research suggests that it may modulate inflammation in IBD via regulation of proinflammatory cytokines[168,169] and may play a role in the prevention of colon cancer.[170]

Beta-Glucuronidase

Beta-glucuronidase is an inducible enzyme elaborated by anaerobic *E. coli, Peptostreptococcus, Bacteroides,* and *Clostridium*.[171,172] By uncoupling glucuronides (xenobiotics and endogenous compounds detoxified via the glucuronidation pathway), this enzyme can deconjugate potential toxins, enhancing the formation of local carcinogens in the bowel[173] and promoting the enterohepatic recirculation of toxins, hormones,[174] and various drugs[175] in the body. For this reason, excess amounts of the enzyme may promote higher risk of colon cancer. Both the incidence of colon cancer and levels of β-glucuronidase tend to be higher in individuals consuming Western diets (high in saturated fat, low in fiber) than in individuals consuming diets high in fiber and low in saturated fat.[176]

However, an adequate amount of β-glucuronidase activity is probably important to maintain normal enterohepatic recirculation of endogenous compounds, such as vitamin D,[177] thyroid hormone,[178] and estrogen.[179]

Bile Acids

The relationship between dietary fat and increased risk of colon cancer is believed to hinge on the excess production of bile acids and the bacterial conversion of conjugated primary bile acids to potentially dangerous unconjugated secondary bile acids.[180] Studies have found that a higher ratio of secondary bile acids, specifically, an elevated ratio of lithocholic acid to deoxycholic acid (LCA/DCA ratio), is associated with higher susceptibility to polyps and colorectal cancer.[181] Increased secondary bile acid excretion and a rise in the LCA/DCA ratio have also been observed in patients with gallstones.[182]

Bacterial overgrowth markedly increases the concentration of unconjugated bile acids, and this mechanism may play an important role in the pathophysiology of gut mucosal injury.[183] Probiotic treatment with *L. reuteri* has been demonstrated to lower the bioavailable concentration of toxic bile acids.[180]

SUMMARY

The philosophical framework that describes GI health to be the foundation of optimal health is not a new one. The *Sushruta Samhita*, an ancient Ayurvedic text, alludes to this in the following passage: "A person whose basic emotional and physical tendencies are in balance, whose digestive power is balanced, whose bodily tissues, elimination functions and activities are in balance, and whose mind, sense and soul are filled with vitality, that person is said to be healthy." If we hold this tenet to be true, then tools that allow us to diagnostically illuminate the imbalances that create symptoms and disease states in our patients—and ultimately lead to interventions to support them—are clinically important. Biomarkers for stool analysis provide a useful approach to identify the underlying pathologies that present as gut dysfunction, thus eliminating the need for costly diagnostic testing where unnecessary, highlighting those individuals specifically at risk for severe disease who do require significant diagnostic intervention, and identifying the source of gut dysfunction to apply simple, cost-effective treatments (Boxes 27-1 and 27-2).

BOX 27-1 Biomarkers for Stool Analysis Clinical Vignettes

A 21-year-old woman presents with a history of intermittent recurrent abdominal cramping, bloating and/or gas, and occasional diarrhea over the past 2 years. She has been evaluated by her college health clinic on numerous occasions, has been told that her symptoms were primarily "stress related," and has been advised to cut back on her coffee intake during the day. She has recently been evaluated for complaints of fatigue, and has been diagnosed with hypothyroidism (including elevated thyroid antibodies), for which she is now being treated. While home during a break, the patient was asked to submit a stool analysis by her primary care doctor who was concerned that some underlying etiology had not been determined. Results were significant for the following:

Pancreatic Elastase = 150 (normal level, more than 200)

- At this level, the pancreatic elastase clinically indicates moderate pancreatic insufficiency and need for pancreatic enzyme support. Evaluation of the underlying cause of pancreatic insufficiency is warranted.

Calprotectin = 22 (normal level, less than 50)

- A normal calprotectin level indicates no inflammation due to neutrophilic activity in the gastrointestinal tract.

Eosinophil Protein X = 13.1 (normal level, less than 7.0)

- An elevated eosinophil protein X may be associated clinically with celiac disease, parasitic infections, and/or immunoglobulin-E mediated food allergies.

Microscopy = No Evidence of Parasite Infection or Altered Gut Flora

Given that celiac disease can be consistent with the patient's clinical symptoms, and may be suggested on stool analysis by an elevated eosinophil protein X and compromised pancreatic exocrine function (low pancreatic elastase), the doctor decided to evaluate the patient for celiac disease. Blood serologies (positive tissue transglutaminase immunoglobulin-A and positive anti-endomysial antibody) confirmed the diagnosis of celiac disease. The patient was placed on a gluten-free diet and given pancreatic digestive enzyme support. At follow-up, the patient reported that her symptoms had markedly improved—appearing only during times of dietary indiscretion.

BOX 27-2 Biomarkers for Stool Analysis Clinical Vignette

A 42-year-old woman presents with a 3-year history of irregular bowel movements and intermittent lower abdominal pain, for which she has seen her primary care provider many times. She also has been diagnosed with depression, and is currently using a tricyclic antidepressant, which she notes does not make a significant difference in her abdominal pain. She has used fiber, antidiarrheals, probiotics, and diet changes in the past to no avail. Upon evaluation, her new primary physician chooses to use stool analysis to evaluate the root cause of her illness. While waiting for the stool test to return, empiric use of probiotics at 10 billion colony-forming units per day has made no difference. The following results were noted:

Pancreatic Elastase = 482 (normal level, more than 200)

- At this level, the pancreatic elastase clinically indicates normal pancreatic function and no need for pancreatic enzyme support.

Calprotectin = 286 (normal level, less than 50)

- This level of elevation of calprotectin level indicates severe gastrointestinal tract inflammation and warrants referral to a specialist for further investigation (i.e., colonoscopy).

Microscopy = No Evidence of Parasitic Infection or Altered Gut Flora

The patient is referred for colonoscopy for inflammatory changes in the gastrointestinal tract. She is diagnosed with ulcerative colitis and placed on steroids and 5-aminosalicylic acid. For this patient, stool analysis allowed for early detection and appropriate referral to a gastroenterologist. Subsequent evaluations of gastrointestinal inflammation with the calprotectin biomarker can be used to monitor mucosal healing and determine if repair is sufficient and/or complete, or to monitor for relapse in patients with IBD.

INTRODUCTION

Urinary organic acid analysis for metabolic profiling was used initially to assess inborn errors of metabolism that can cause severe mental retardation or death within the first year of life. The identification of isovaleric acidemia in 1966 was followed quickly by numerous additional acidurias, because the severe enzyme impairments of genetic diseases were found to result in urinary excretion of highly elevated amounts of organic compounds.[1] Profiling of organic acids in urine as a routine laboratory evaluation of chronic diseases is a relatively recent addition to clinical assessment procedures.

Levels of organic acids in urine can be used to detect functional nutritional deficiencies, to identify genetic variants, and to establish the source of toxicants from the environment and gut.[2-4] For example, elevated methylmalonic acid (MMA) in urine is a sensitive indicator of functional vitamin B_{12} deficiency because the vitamin plays a critical role in metabolic clearance of MMA.[5,6] Similarly, levels of other organic acids in urine are markers of multiple nutritional deficiencies. Organic acid profiling of urine has been found useful in numerous clinical evaluations, as shown in Table 28-1.

URINARY ORGANICS PROFILING

The test is performed on an overnight urine sample and the concentrations of 40 or more compounds are measured by gas chromatography/mass spectrometry (GC/MS) or liquid chromatography (LC)/MS-MS methods. The information content of the profile is high, but the interpretation is simplified if one keeps in mind that the results answer six questions of clinical relevance:

1. Is mitochondrial energy production adversely affected?
2. Are functional nutrient deficiencies present?
3. Are neurotransmitters displaying abnormal turnover rates?
4. Is antioxidant protection status insufficient?
5. Is toxicant exposure elevated?
6. Are there elevated growth rates of upper intestinal bacteria or fungi?

Table 28-2 shows compounds that might appear on a typical quantitative report of organics in urine with some interventions that have been found to help rectify conditions associated with abnormal levels. The supplementary nutrient amounts are given as guides to starting points that might improve clinical outcomes for adults.

FATTY ACID OXIDATION

Adipate, Suberate, and Ethylmalonate

Adipate and suberate are short-chain dicarboxylic fatty acids produced by an alternate oxidation pathway called ω-oxidation, which occurs in peroxisomes. Their production is normally low because the predominant pathway is β-oxidation in the mitochondria. However, transport of fatty acids into the mitochondria requires carnitine as a carrier. Suboptimal levels of carnitine result in inadequate transfer of fatty acids into the mitochondria and subsequent

TABLE 28-1 **Clinical Applications of Organic Acids in Urine Testing**

CONDITION	COMPOUND(S)	REFERENCE(S)
Acidosis with metformin	Lactate	81, 82
Acute appendicitis	5-Hydroxyindoleacetate	83
Adult neurologic complaints and breathing problems	Pyroglutamate	84
Alcoholic delirium tremens	Vanillylmandelate, homovanillate	85
Anemia	Methylmalonate	86
Arginine-responsive hyperammonemia	Orotate	88
Attention deficit hyperactivity disorder	Homovanillate	87, 89
Bacterial overgrowth syndromes in acutely ill infants and children	*p*-Hydroxyphenylacetate	90
Biotin-responsive orificial skin lesions, lethargy, hypotonia, and alopecia	3-Hydroxyisovalerate	91
Birth asphyxia	Lactate, pyruvate, 3-hyroxybutyrate, 4-hydroxyphenyllacetate, 2-hydroxybutyrate, 2-oxo-isocaproate, 2-oxo-3-methylvalerate	92
Calcium urolithiasis	Citrate	93
Carnitine-responsive familial Reye-like syndrome	Pyruvate, α-ketoglutarate, α-ketoadipate	94
Cerebral palsy	Fumarate	95
Chronic fatigue syndrome	Succinate	96
Chronic lactic acidosis (weakness, shortness of breath)	Alpha-ketoglutarate, α-hydroxybutyrate	97
Encephalomyelopathy	Alpha-ketoglutarate, succinate, adipate, suberate	98
Encephalopathy	D-Lactate	99
Folate deficiency developmental disorders	5-Hydroxyindoleacetate, homovanillate	100
Glycine-responsive malnutrition	Pyroglutamate	101
Gut flora and *Klebsiella*-specific metabolites	Benzoate, phenylacetate, *p*-hydrophenylpropionic, dihydroxyphenylacetate	102, 103
Hemoblastoses and nephroblastoma	*p*-Hydroxyphenyllactate	104
Hepatic detoxification	Pyroglutamate	105
Phenol exposure	*o*-Cresol	106
Pregnancy decrease of biotin status	3-Hydroxyisovalerate	107
Recent alcohol use	5-Hydroxyindoleacetate	108
Riboflavin-responsive inspiratory stridor	Ethylmalonate	109
Sleep-waking rhythm	Tartrate	110
Thiamin-responsive maple syrup urine disease	Alpha-ketoisovalerate	111
Toluene exposure	Hippurate	112
Vitamin deficiency in the elderly	Homocysteine, 2-methylcitrate	113
Xylene exposure	2-Methylhippurate	114

TABLE 28-2 **Quick Reference to Clinical Significance of Abnormal Levels of Organics in Urine**

NAME	ABNORMALITY	POTENTIAL INTERVENTION*	METABOLIC PATHWAY
Carbohydrate Metabolism			
Lactate	H	CoQ_{10}, 50 mg tid	Mitochondrial electronic transport system
Pyruvate	H	B complex, 1 capsule tid; B_1, 100 mg tid; lipoic acid, 100 mg tid	Aerobic/anaerobic energy production
Beta-hydroxybutyrate	H	Chromium picolinate, 200 mcg bid	Ketosis
Fatty acid oxidation			
Adipate, suberate, ethylmalonate	H	L-Carnitine, 250 mg tid; B_2, 100 mg bid; B_5, 500 mg bid; choline, 100 mg tid; vitamin C, 1000 mg tid; CoQ_{10}, 150 mg	Mitochondrial vs peroxisomal fatty acid oxidation
Energy Production			
Citrate	L	Aspartic acid, 500 mg	Anaplerotic
Cis-aconitate	H	Arginine, 1000 mg; iron, 18 mg; *N*-acetylcysteine, 1000 mg bid	Citric acid cycle

TABLE 28-2 Quick Reference to Clinical Significance of Abnormal Levels of Organics in Urine—cont'd

NAME	ABNORMALITY	POTENTIAL INTERVENTION*	METABOLIC PATHWAY
Isocitrate	H	Arginine, 1000 mg; B_3, 100 mg Magnesium, 400 mg; manganese, 20 mg	Citric acid cycle
Alpha-ketoglutarate	L	Alpha-KG, 300 mg; glutamine, 1-5 g	Anaplerotic
	H	B-complex, 1 tid; lipoic acid, 100 mg	Citric acid cycle
Succinate	L	Isoleucine, 1000 mg tid; valine, 1000 mg tid	Anaplerotic
	H	Magnesium, 500 mg	Citric acid cycle
Fumarate	L	Tyrosine, 1000 mg bid; phenylalanine, 500 mg bid	Anaplerotic
Malate	H	B_3, 100 mg tid	Citric acid cycle
Specific Vitamin Indicators			
Alpha-ketoisovalerate, α-ketoisocaproate, α-keto-β-methylvalerate	H	B complex, 1 capsule tid; B_1, 100 mg tid; lipoic acid, 100 mg tid	BCAA catabolism
Kynurenate	H	B_6, 100 mg	Kynurenin
Xanthurenate	H	B_6, 100 mg	Kynurenin
Beta-hydroxyisovalerate	H	Biotin, 5 mg bid; magnesium, 100 mg bid	Isoleucine catabolism
Methylmalonate	H	B_{12}, 1000 mcg tid	Leucine catabolism
FIGLU	H	Folic acid	Histidine catabolism
Hydroxymethylglutarate	H/L	CoQ_{10}, 50 mg tid	Cholesterol and CoQ_{10} biosynthesis
Detoxification indicators			
Glucarate	H	Glycine, GSH, NAC, 500-5000 mg/day	Detoxifying liver enzyme induction
Orotate	H	Alpha-KG, 300 mg tid; arginine, 1-3 g/day; aspartic acid, 500 mg bid; magnesium, 300 mg	Ammonia clearance by urea cycle vs pyrimidine synthesis
p-Hydroxyphenyllactate	H	Vitamin C up to 100 mg/kg	Prooxidant and carcinogen
2-Methylhippurate	H	Avoidance of xylene	Hepatic glycine conjugation
Alpha-hydroxybutyrate	H	NAC, 1000 mg; glutathione, 300 mg; lipoic acid, 600 mg Taurine, 500 mg bid; glutathione, 300 mg	Hepatic glutathione synthesis
Pyroglutamate	H		Glutathione-requiring γ-glutamyl pathway
Sulfate	L		Glutathione turnover
Neurotransmitter Metabolism			
Vanilmandelate, homovanillate	L/H	Tyrosine may stimulate rates of catecholamine production; contraindicated for patients taking MAO inhibitors	Catecholamine catabolism, neurotransmitter metabolites
5-Hydroxyindolacetate	L	5-Hydroxytryptophan can stimulate rates of serotonin production; contraindicated for patients taking SSRI	Serotonin catabolism by monoamine oxidase
Quinolinate	H	Magnesium, 300 mg	Kynurenin
Dysbiosis Markers (Products of Abnormal Gut Microflora)			
Products of bacterial growth: benzoate, hippurate, phenylacetate, phenylpropionate, *p*-hydroxybenzoate, *p*-hydroxyphenylacetate, tricarballylate, *p*-hydroxyphenylproprionate D-lactate Products of yeast growth D-Arabinital	H	If any of these compounds is high, the possibility of dysbiosis is reinforced. Glutamine, 10-30 g daily, and free-form amino acids normalize gut permeability. Take appropriate steps to ensure favorable gut microflora population.	Numerous interferences in pathways and cellular energy control mechanisms

BCAA, branched chain amino acids; bid, twice daily; CoQ_{10}, coenzyme Q_{10}; FIGLU, formiminoglutamate; GSH, glutathione; H, high; KG, ketoglutarate; L, low; MAO, monoamine oxidase; NAC, N-acetyl-L-cysteine; SSRI, selective serotonin reuptake inhibitor; tid, three times a day.

*Supplemental dosages are in the upper range of aggressive repletion.

compensation via ω-oxidation, producing elevated urinary levels of adipate and suberate. Similar carnitine transport impairment leads to elevation of urinary ethylmalonate. Urinary concentrations of all three of these compounds are elevated in overt enzyme failure, but the patterns of elevations in milder carnitine deficiencies vary.

Symptoms include periodic mild weakness, nausea, fatigue, hypoglycemia, "sweaty feet" odor, recurrent infections, and increased free fatty acids. Patients may also exhibit a Reye-like syndrome with dicarboxylic aciduria, which has been associated with various metabolic toxins generated from viral infections that affect mitochondrial function. Mild heterozygotic forms of dicarboxylic aciduria may be commonly seen clinically and may go unrecognized. The enzymes involved also respond to environmental toxin exposure with altered lipid metabolism, which can lead to impaired immune responsiveness.[7,8] Supplementation of carnitine and riboflavin is indicated when urinary adipate, suberate, or ethylmalonate is elevated. (See Chapter 74 for a full discussion of this useful nutrient.)

CARBOHYDRATE METABOLISM

Lactate and Pyruvate

For each molecule of glucose carried through the glycolytic pathway, two molecules of pyruvate are produced. The conversion of pyruvate into acetyl-coenzyme A requires the pyruvate dehydrogenase enzyme complex that is dependent on cofactors derived from thiamin, niacin, riboflavin, pantothenic acid, and lipoic acid. Elevations of pyruvate may reflect failure of the enzyme because of a functional need for increased B vitamins, particularly thiamin and pantothenic acid. Levels of pyruvate in the tissues are further controlled by the biotin-containing protein pyruvate carboxylase, which controls the first step in the formation of glucose from pyruvate. Multiple forms of pyruvate carboxylase deficiency, some of which are biotin responsive, have been reported.[9]

Any accumulation of pyruvate can lead to concurrent elevations of lactate through the action of lactate dehydrogenase. Lactate accumulates when there is a block in the final oxidative phosphorylation (ox/phos) stage of energy production. Such a block results in inactivation of the citric acid cycle (CAC). Coenzyme Q_{10} (CoQ_{10}) has been used in cases of lactic acidosis associated with ox/phos impairments.[10,11] Increased lactate is a common acidotic condition that can be caused by a variety of metabolic problems. Decreased lactate is seen in people who are physically inactive. Highly trained athletes have such efficient conversion of lactate to glucose that they have lactate levels below the 2.5 percentile.

Beta-Hydroxybutyrate

Beta-hydroxybutyrate is a ketone body that becomes elevated in conditions of impaired glucose oxidation, where free fatty acids are used as the predominant energy source. Ketone bodies can be thought of as a transportable form of acetate resulting from oxidation of fatty acids. Elevations of β-hydroxybutyrate seen in overnight collection urine specimens might indicate inefficient use or mobilization of carbohydrate stores. Excessive fatigue on exertion is the most common symptom associated with ketosis. Chromium and vanadium supplementation may support carbohydrate use by improving insulin receptor activation.

CENTRAL ENERGY PATHWAY INTERMEDIATES

Citrate, Isocitrate, Alpha-Ketoglutarate, *cis*-Aconitate, Succinate, and Fumarate

Citrate, isocitrate, α-ketoglutarate (α-KG), *cis*-aconitate, succinate, and fumarate are intermediates in the CAC. Most of the enzymes of the CAC require specific vitamin-derived cofactors and minerals for their function. When the enzyme rates slow due to deficiency of their cofactors, abnormal spilling of CAC intermediates into urine can occur. For example, in cytochrome C oxidase deficiency, there is inefficient removal of the primary product of the CAC, reduced nicotinamide adenine dinucleotide, and citrate, malate, fumarate, and α-KG all increase.[12] CoQ_{10} deficiency can also result in elevations of CAC intermediates (see section on Hydroxymethylglutarate). Aggressive dosing with carnitine, CoQ_{10}, and other nutrients has been used to help normalize mitochondrial function in genetic mitochondriopathies.[23]

Mild inborn errors of energy metabolism that may be compatible with survival, at least into young adulthood, but not with normal development of mental and neurologic functions, have been associated with the excretion of elevated α-KG.[24] The clinical heterogeneity of neurometabolic disorders and the importance of organic acid analysis in the diagnosis of static encephalopathy were underscored by the finding of excretion of excess fumaric acid in a 5-year-old girl with a previous diagnosis of cerebral palsy.[25]

Urinary levels of citrate, a marker of acid-base status, normally decrease with age.[26] Metabolic compensation in glycogen storage disease type 1a leads to low urinary citrate concentration and higher incidence of nephrolithiasis. Citrate supplementation may help avoid urinary calculi in patients with low urinary citrate levels.[27] Drinking bicarbonate-rich mineral water has also been shown to help raise urinary citrate concentration, and this dietary change has been suggested to prevent the recurrence of calcium oxalate and uric acid stones.[28]

Intermediates of the cycle can also be derived from amino acids. This may explain the energy-boosting effect that some individuals report when they take free-form amino acid supplements. The effect results from the conversion of specific amino acids directly into CAC intermediates needed for the energy-producing cycle. The fatigue-reducing effect of supplementation of aspartate salts and α-KG acid has been attributed to such a mechanism.[9,20] Supplementation of the precursors serves to drive the cycle and generate reducing equivalents used in the electron transport chain in which adenosine triphosphate is produced via oxidative phosphorylation.

Hydroxymethylglutarate

Hydroxymethylglutarate (HMG) is the metabolic precursor of cholesterol and CoQ_{10}. Low levels may reflect inadequate synthesis and possible deficiency of CoQ_{10}. The statin drugs lower cholesterol by blocking the conversion of HMG into mevalonate. They cause elevated urinary HMG and lowered serum CoQ_{10} levels.[21] CoQ_{10} is used in the mitochondrial oxidative phosphorylation pathway for adenosine triphosphate synthesis and is a potent antioxidant because it lowers the undirected flow of electrons onto molecular oxygen. It has been employed extensively as a cardiovascular protective agent.[22]

CoQ_{10} has also been used successfully to improve mitochondrial function in clinical situations of cardiac and skeletal muscle weakness and cramping, and in the extreme, mitochondrial encephalomyopathy.[23,24] The coenzyme has been found helpful in the treatment of fatigue, particularly when both lactate and

pyruvate are elevated. Such responses reflect the inability of mitochondrial oxidative phosphorylation to proceed efficiently, possibly because of CoQ_{10} deficiency.

B-COMPLEX INSUFFICIENCY MARKERS

Alpha-Ketoisovalerate, Alpha-Ketoisocaproate, and Alpha-Keto-Beta-Methylvalerate

Ketoacids derived from the branched chain amino acids isoleucine, leucine, and valine are α-ketoisovalerate, α-ketoisocaproate, and α-keto-β-methylvalerate, respectively. They are formed by the removal of the amine group in branched chain amino acid catabolism and are excreted in large amounts along with their amino acid precursors in the inherited disorder known as maple syrup urine disease. There are several known metabolic disorders in the pathways of catabolism of the ketoacids. The reactions require enzymes similar to pyruvate dehydrogenase that use the B-complex cofactors B_1, B_2, B_3, B_5, and lipoic acid. Elevations of the branched chain ketoacids provide a functional assessment of the sufficiency of these vitamins, especially thiamin.[25]

INDICATORS OF A SPECIFIC VITAMIN DEFICIENCY

Beta-Hydroxyisovalerate

Beta-hydroxyisovalerate is an ideal marker compound for evaluating biotin status because it is produced in the high-flux pathway for degradation of the most abundant dietary amino acid, isoleucine. The carboxylase enzyme that is necessary for the step that clears β-hydroxyisovalerate requires the active form of biotin; human biotin deficiency has been shown to quickly produce elevation of urinary β-hydroxyisovalerate.[26] Beta-hydroxyisovalerate is elevated in inherited disorders of multiple carboxylase insufficiency because biotin is the cofactor for the mitochondrial carboxylase enzymes.[27] Symptoms of multiple carboxylase deficiencies include alopecia, rash, *Candida* dermatitis, unusual odor to the urine, immune deficiencies, and muscle weakness. Biotin deficiencies of various degrees develop in a substantial minority of normal pregnancies and in patients receiving long-term therapy with anticonvulsants.[26,28] Other possible indications of biotin deficiency are elevations of lactate and alanine in urine and accumulations of odd-chain fatty acids in plasma or red cell membranes.[29] Supplementation of biotin may improve these conditions.

Methylmalonate

Methylmalonate is converted into succinic acid by means of a vitamin B_{12}–dependent enzyme, methylmalonyl CoA mutase. The lack of vitamin B_{12} impairs this conversion, leading to elevation of urinary methylmalonate.[30] If both homocysteine and methylmalonate are elevated, both vitamin B_{12} and folate functional deficiencies are indicated. Folate supplementation is suggested if homocysteine alone is high, and vitamin B_{12} supplementation is needed if methylmalonate alone is elevated.

Formiminoglutamate

Formiminoglutamate (FIGLU) is a biochemical marker of folic acid deficiency. Histidine metabolism is interrupted in the absence of adequate levels of folic acid, causing accumulation of FIGLU acid elevation of levels in urine.[31] Because of the linkage between folate and vitamin B_{12}, FIGLU may be a more sensitive marker for vitamin B_{12} deficiency than methylmalonate. In a cohort of 15 leukemia cases, three patients showed elevated FIGLU, whereas the entire group had normal methylmalonate levels.[32] A child with failure to thrive and vomiting had a genetic variant in the vitamin B_{12}–dependent FIGLU transferase enzyme in which normal serum folate and vitamin B_{12} values were present with gross excretion of FIGLU.[33]

Kynurenate and Xanthurenate

The hepatic kynurenin pathway that is responsible for clearing excess tryptophan is impaired by vitamin B_6 deficiency in such a way that the intermediates, kynurenate and xanthurenate, accumulate and spill into urine. These two markers are much higher in the kidney than in blood. The precursors kynurenine and 3-hydroxykynurenine are formed in the liver, but they appear in urine as total kynurenine.[34] As xanthurenate excretion increases, niacin production from tryptophan decreases.[35] Pregnancy may have independent effects on kynurenine excretion, and studies in rats indicate that the effects of pregnancy and diet are additive.[36]

NEUROTRANSMITTER METABOLISM

Vanilmandelate and Homovanillate

Vanilmandelate (VMA) (also called vanillylmandelate) is the principal metabolite of the catecholamine epinephrine. Low urinary levels have been associated with low central nervous system (CNS) levels of the neurotransmitter. Symptoms associated with this condition are depression, sleep disturbances, inability to deal with stress, and fatigue. Treatments aimed at improving protein digestion and supplementation of the amino acid precursors can normalize neurotransmitter levels in the CNS.[37] The much more commonly encountered conditions of elevated adrenal gland output resulting from chronic stress produce high urinary levels of VMA. Because of the rapid clearance rate for this hormone, high VMA indicates an elevated catecholamine turnover rate, but does not necessarily indicate elevated concentration of the hormones in blood.

Homovanillate (HVA) is the principal product of dopamine catabolism. Elevated urinary values indicate increased production and turnover of dopamine. VMA is highly elevated by pheochromocytomas, and both VMA and HVA are measured in screening and prognosis for hemoblastoses and neuroblastoma.[38,39]

5-Hydroxyindolacetate

Catabolic breakdown of serotonin leads to excretion of 5-hydroxyindoleacetate (5-HIA). Abnormally high levels of this metabolite result from increased rates of serotonin release from the CNS, argentaffin cells in the gut, or platelets. Carcinoid tumors composed of chromaffin tissue can also release large amounts of serotonin. Serotonin is necessary for control of gut motility because it activates smooth muscle activity. Inadequate production of serotonin leads to constipation. Low levels have also been associated with depression, fatigue, insomnia, suicide, attention deficit disorder, and behavioral disorders. When 5-HIA levels are low, dietary therapy should focus on improving protein digestion and increasing consumption of foods high in tryptophan. (See Chapter 58 for discussions of hypochlorhydria and pancreatic insufficiency.) These actions minimize the need for oral tryptophan or 5-hydroxytryptophan use.

Quinolinate and Picolinate

The hepatic kynurenin pathway that was previously mentioned as the origin of urinary xanthurenate and kynurenate is also operative in the brain. However, the normal end products in the brain are quinolinic and picolinic acids that serve to modulate brain activity via regulating *N*-methyl-D-aspartate (NMDA) receptors. In contrast to the unreliability of other neurotransmitter levels in urine for assessing CNS status, urinary quinolinate and picolinate are directly related to their concentrations in the brain, where their formation is specifically stimulated by the inflammatory cytokine interferon-γ.[12] Urinary quinolinate rises in parallel with neopterin as both compounds reflect the process of inflammation.[40] However, quinolinate is a specific agonist for glutamatergic *N*-methyl-D-aspartate receptors, thus contributing directly to the hyperexcitation of inflammation in the brain.[41]

INDICATORS OF DETOXIFICATION FUNCTION

Glucarate

Glucaric acid (glucarate) is the oxidation product of glucuronic acid. It is a by-product of the predominant liver Phase II detoxification reactions involving glucuronic acid conjugation. A great variety of drugs, environmental toxins, food components, and products of gut microbial metabolism are prepared for excretion by glucuronidation. Decreased glucarate is an indicator of reduced overall hepatic function, whereas elevation of this compound is an indication of enzyme induction caused by potentially toxic exposures.[42,43]

The excretion of D-glucarate is considered a marker of the viability of hepatocytes and is a useful clinical prognostic predictor in biliary atresia.[44] Most exposures that result in stimulation of hepatic cytochrome P-450 activity result in increased excretion of glucarate. For example, urinary D-glucarate is elevated in pesticide-exposed groups.[45] Patients with clinically quiescent chronic pancreatitis also show elevations of urinary glucarate, indicating a relationship of toxic metabolite stress to heightened free radical activity and hence to the genesis of chronic pancreatitis.[46] Glucarate measurements have been advanced as useful biomarkers to xenobiotic exposure, being particularly useful as a screening tool in reproductive epidemiology.[47]

Orotate

Orotic acid accumulation is a sensitive marker of ammonia buildup. Ammonia (via glutamine) is normally disposed of by forming carbamoyl phosphate, which enters the urea cycle. When there is insufficient capacity for detoxifying the load of ammonia, carbamoyl phosphate leaves the mitochondria and stimulates the synthesis of orotic acid.[48] Increased orotic acid production is a sensitive indicator of arginine availability. Most of the symptoms that develop after arginine deprivation can largely be accounted for by a diminished efficiency of ammonia detoxification. Greater orotic biosynthesis was observed with rising ammonia concentrations in rat, mouse, and human livers, and was reduced by in vitro arginine supplementation.[49]

Genetic medium-chain acyl CoA dehydrogenase deficiency and other disorders of fatty acid oxidation may appear long after infancy in some patients, such as those with a clinical diagnosis of Reye's syndrome. These disorders may mimic defects in the urea cycle, such as that reported for a 13-year-old girl with hyperammonemic encephalopathy and orotic aciduria caused by ornithine transcarbamylase deficiency.[50] Responses should include steps to stimulate ureogenesis, including α-KG, magnesium, and aspartic and glutamic acids.

p-Hydroxyphenyllactate

p-Hydroxyphenyllactate (HPLA) is a carcinogenic metabolite of tyrosine that increases lipid peroxidation in the liver.[51] Methyl *p*-hydroxyphenyllactate (MeHPLA) is an important cell growth–regulating agent, and tumor cells contain esterase enzymes that hydrolyze the compound to the free acid, HPLA.[52] HPLA is an important regulator of normal and malignant cell growth, and it appears to mediate the cancer-promoting effects of estrogen. MeHPLA blocks uterine growth in vivo and inhibits growth of MCF-7 human breast cancer cells in vitro.[53] High doses of ascorbic acid (100 mg/kg body weight daily) were shown to arrest or significantly inhibit the excretion of HPLA in patients with hemoblastoses and nephroblastoma.[54] HPLA may also be produced by some microbes that could inhabit the gut, but the cell proliferative and prooxidant functions are of greater clinical relevance.[55]

2-Methylhippurate

2-Methylhippurate is a biotransformation metabolite of the common solvent xylene. Elevations indicate an exposure to this potentially toxic compound.[56,57] Although there are three positional isomers of xylene, the ortho form is virtually always present, so only the 2-methyl isomer of hippurate is necessary for detecting and monitoring exposure to the solvent.[58] A study of spray painters showed elevated methylhippurate, indicating recent exposure to xylene.[59] Patient counseling in avoidance of these compounds is indicated. Glycine supplementation may also be considered to ensure maximal rates of conjugation to clear body burdens of xylene. This is especially the case when benzoate is found elevated in urine (see discussion of benzoate later).

Alpha-Hydroxybutyrate

Alpha-hydroxybutyrate is a by-product of the conversion of cystathionine to cysteine for hepatic glutathione synthesis. When demand for glutathione increases due to oxidative stress or detoxification requirements, the flow through this pathway increases with concomitant increases in the excretion of α-hydroxybutyrate. The enzyme α-hydroxybutyrate dehydrogenase occurs at high concentrations in cardiac muscle tissue, and its elevation in serum is widely used to estimate infarct size and reperfusion effectiveness.[60] A series of urinary organic acid profiles performed on an autistic child exposed to xylene indicated that α-hydroxybutyrate was excreted at higher levels when epinephrine was stimulated.[61] These findings are consistent with observations of α-hydroxybutyrate dehydrogenase changes in mice caused by acute stress.[62]

Pyroglutamate

Pyroglutamate (sometimes called 5-oxoproline) is a cyclic form of glutamic acid. Small amounts are always present in overnight urine because the substance is produced as an intermediate in the γ-glutamyl cycle used in a renal recovery pathway involving active transport of amino acids.[63] This process uses glutathione as a carrier and requires glycine to reform glutathione. When glycine is insufficient, there is net conversion of glutathione to pyroglutamate, so this pathway conserves amino acids at the expense of glutathione. Pyroglutamaturia in an adult receiving antibiotic therapy is evidence for a renal-associated mechanism.[64] Other

cases of pyroglutamaturia accompanying homocystinuria indicate a glutathione-wasting mechanism leading to elevated urinary pyroglutamate.[65] Supplemental glycine and *N*-acetylcysteine can replenish the intermediates in the γ-glutamyl cycle and help rebuild total body glutathione.[66,67]

Sulfate

Urinary sulfate is an inorganic compound sometimes reported on profiles of organic acids. It is measured in a separate assay and is included because of its added value in assessing the functioning of the detoxification pathways. Sulfation pathways are used in Phase II liver detoxification for the biotransformation of drugs, steroid hormones, and phenolic compounds, among others. Urinary sulfate has been used to assess the body's reserve of sulfur-containing compounds (especially glutathione) used in Phase II pathways. These stores need replenishment when the sulfate/creatinine ratio is low. Administration of glutathione, in combination with oral cysteine, taurine, and salts of sulfate, is used to replenish sulfur pathways and restore the hepatic supply of inorganic sulfate.[68,69] Glutathione levels in the liver can be increased 35% in normal individuals by supplementation of *Silybum marianum* (see Chapter 123).

PRODUCTS OF GUT MICROFLORA

Several studies have used the appearance of unique products of microbial metabolism in urine as an indicator of the abnormal overgrowth of unfavorable intestinal microflora, a condition sometimes called "gastrointestinal dysbiosis." Such a condition has been related to a wide variety of symptoms due to pathogenic toxins produced by the populations of microflora. For example, no false-negative results and only 2% of false-positive results for small bowel disease and bacterial overgrowth syndrome were found in a study of urinary *p*-hydroxyphenylacetate in 360 acutely ill babies and children.[70] Some compounds are absorbed and enter the detoxification pathways of the liver to be excreted as products that can serve as sensitive indicators of changes in gastrointestinal flora.[71]

Phenylacetate, Phenylpropionate, *p*-Hydroxybenzoate, *p*-Hydroxyphenylacetate, *p*-Hydroxyphenylpropionate, and Tricarballylate

For individuals with normal, healthy intestinal function, the compounds phenylacetate, phenylpropionate, *p*-hydroxybenzoate, *p*-hydroxyphenylacetate, *p*-hydroxyphenylpropionate, and tricarballylate should not appear as more than background concentrations in urine. Except for tricarballylate (derived from dietary carbohydrates), they are produced by microbial action on dietary polyphenolic compounds and all are markers of bacterial growth in the gut. *p*-Hydroxyphenylacetic aciduria has been found useful in detecting small bowel disease associated with *Giardia lamblia* infestation, ileal resection with blind loop, and other diseases of the small intestine associated with anaerobic bacterial overgrowth.[70] Use of antibiotics such as neomycin, which acts primarily against aerobic bacteria, can encourage the growth of *Giardia* and anaerobic bacteria, which then produce greater amounts of these compounds.[72]

Other gastrointestinal disorders, including cystic fibrosis of the pancreas, celiac disease, and unclassified enteritis, have been associated with increased excretion of *p*-hydroxybenzoate, phenylacetate, and *p*-hydroxyphenylacetate. Patients with cystic fibrosis had elevations of *p*-hydroxyphenylacetate even while undergoing pancreatin therapy. Variations in the relative amounts of these compounds observed with this type of gastrointestinal disturbance are an indication that the patterns of excretion are apparently determined by the microbial flora present in the patient's intestinal lumen.[73] Tricarballylate is produced by aerobic bacteria that quickly repopulate in the gut of germ-free animals.[74] Tricarballylate build up due to overgrowth of *Acidaminococcus fermentans* or *Selenomonas ruminantium* in the lumen of sheep produced magnesium deficiency that could be fatal.[75] Tricarballylate lowers magnesium because of tight binding in the gut and in blood. Magnesium absorption is reduced and excretion is increased.

D-Arabinitol Versus Arabinose

Arabinitol is a sugar alcohol that is a product uniquely produced by anaerobic fungal growth in the gut. D-Arabinitol is produced by fungal metabolism, and detection of elevated urinary D-arabinitol is considered the optimal way of monitoring immunocompromised patients for invasive candidiasis.[76,77] In contrast, arabinose is a carbohydrate that has no relationship to growth of any form of yeast or fungi in or on the human body, although some laboratories may report the compound as a marker.

D-Lactate

Like many other normal human intestinal bacteria, *Lactobacillus acidophilus* produces the D-isomer of lactic acid from the fermentation of undigested dietary carbohydrate. *L. acidophilus* is usually regarded as a favorable organism because moderate amounts of D-lactate can be racemized to L-lactate and oxidized to carbon dioxide by intestinal and hepatic enzymes. The organism produces other desired products and helps discourage colonization by pathogens. Under conditions of carbohydrate malabsorption, however, D-lactate output can exceed metabolic conversion capacity and accumulate, causing systemic acidosis and encephalopathy.[78,79] Elevated urinary D-lactate is characteristic of this condition. Other bacteria, such as *Bacteroides fragilis* and *Klebsiella,* also can produce D-lactate, but they lack the ability to proliferate in the highly acidic environment created by high accumulations of lactic acid. D-Lactic encephalopathy has been found in a high percentage of patients with short bowel syndrome after intestinal resection, and high D-lactate excretion has been found in antibiotic-associated diarrhea.[80]

SUMMARY

Measurement of organics in the urine has become an indispensable clinical tool. The profile provides a wide array of metabolic functional markers at a relatively low cost. Multiple factors involved in energy production, carbohydrate metabolism, functional nutritional status, fatty acid metabolism, detoxification, gut biosis, and neurotransmitter metabolism can be assessed from a single overnight urine specimen. Many of the detected abnormalities can be corrected through the appropriate use of dietary changes, lifestyle improvements, and nutritional and botanical supplements.

INTRODUCTION

Toxic chemicals affect human biochemistry at any level of long-term exposure. Fortunately, the body has mechanisms for transforming, eliminating, or compartmentalizing the many toxic chemicals encountered over a lifetime. Nonetheless, these "safety" mechanisms may be inadequate or even inappropriate in modern industrialized society, especially for susceptible people such as the elderly, individuals with poor nutritional habits, and others who are physiologically stressed.[1,2]

Recognizing and identifying offending chemical(s) can present a difficult challenge for the clinician. Many chemicals exert their effect at such low concentrations that they escape detection except by very sophisticated laboratory methods. Although measuring effects of toxicity by observing symptoms is a time-honored procedure, determination of the actual toxicant often requires the use of laboratory methods that measure biomarkers, which are specific indicators of the toxicant's action.

Porphyrins measured in urine serve as such a biomarker. Porphyrins are particularly well suited as biomarkers for two reasons. First, they are produced in the highly active heme pathway, so any disturbance tends to cause rapid and relatively large accumulations of intermediates. Second, some of the enzymes of the porphyrin-producing pathway are highly sensitive to the presence of various toxins, and they are rapidly turned over. Their short half-lives of minutes or hours cause a demand for rapid synthesis in response to changing environmental signals. The enzymes normally associate with nutrient metal ions to produce heme and cobalamin (and, in plants, chlorophyll), sometimes called the pigments of life.[3]

The presence or elevation of various urinary porphyrin species can flag a potentially toxic condition. Metals and other toxic chemicals with prooxidant reactivity can inactivate porphyrinogenic enzymes, deplete glutathione and other antioxidants, and increase oxidant stress, all of which lead to damage to membranes, enzymes, and other proteins in cells.[4,5] In addition, porphyrinogens (precursors to porphyrins in the reduced state) themselves are easily nonenzymatically oxidized to porphyrins by toxic metals such as mercury. Thus, the distribution pattern of porphyrins in the urine serves as a functional fingerprint of toxicity.[6]

The utility of urinary porphyrin measurement as a diagnostic tool is not new; its use has been documented in the literature since 1934. Specific diseases collectively known as the *porphyrias*, which can be inherited or acquired (e.g., acute intermittent porphyria, porphyria cutanea tarda, variegate porphyria), are often diagnosed with the aid of information about the distribution profile of individual porphyrin species in human urine.

DEFINITIONS

Porphyrins are oxidized by-products that have escaped from the heme biosynthetic pathway, an essential pathway occurring in all nucleated mammalian cells. Heme is the all-important iron-binding molecule essential for the proper function of many proteins, including hemoglobin (oxygen transport), cytochrome c (energy production), and cytochrome P-450 (detoxification). Biosynthesis of heme involves eight enzymes (Figure 29-1), five of which produce intermediate molecules that are collectively called *porphyrinogens*. Some porphyrinogens escape the

intracellular pathway to become oxidized by other cellular processes to porphyrins. In turn, some porphyrins are excreted in urine and feces.

The different molecular species of porphyrins that occur in the urine of healthy individuals form a predictable, characteristic pattern. An elevation of one or more porphyrins is designated *porphyrinuria*. The term *porphyria* is reserved for primary conditions exhibiting specific clinical symptoms caused by an inherited defect in one or more of the heme biosynthetic enzymes. *Porphyrinopathy* is an umbrella term for any disorder in porphyrin metabolism. Enzymatic defects associated with common porphyrias are listed in Table 29-1.

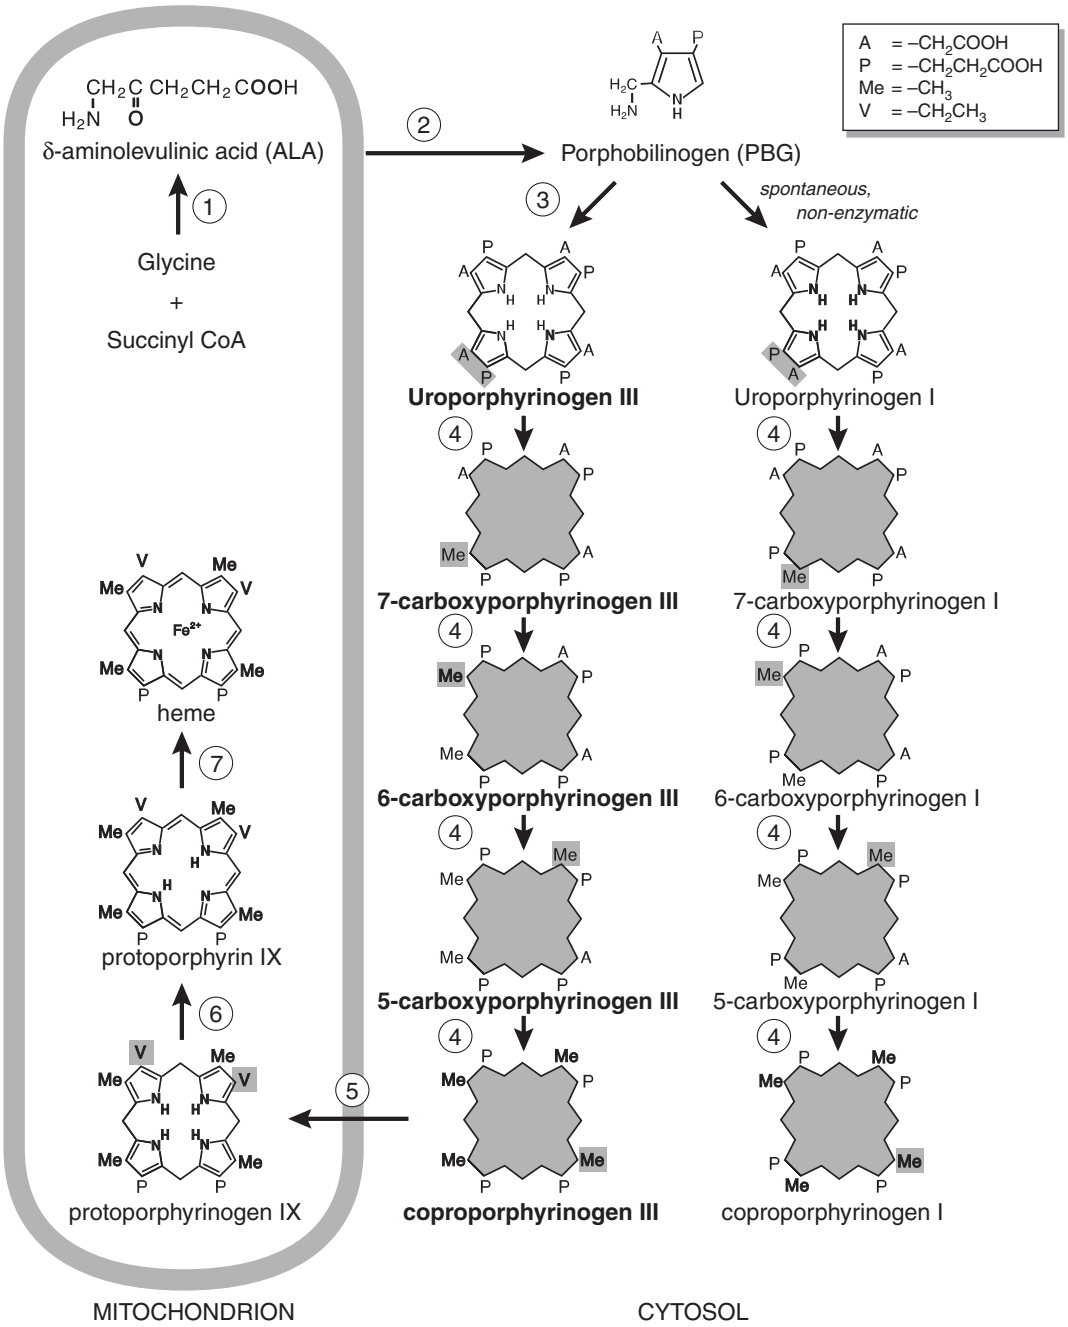

FIGURE 29-1 Biosynthesis of heme. The enzymes that drive the heme pathway are: (1) δ-aminolevulinate (ALA) synthetase; (2) ALA dehydratase; (3) uroporphyrinogen I synthetase (porphobilinogen deaminase) and uroporphyrinogen III cosynthetase, two enzymes that work in concert; (4) uroporphyrinogen decarboxylase; (5) coproporphyrinogen oxidase; (6) protoporphyrinogen oxidase; and (7) ferrochelatase (heme synthetase). Spilled porphyrins derived from porphyrinogens with 8-, 7-, 6-, 5-, and 4-carboxyl groups are largely excreted in the urine, whereas the less polar 2-carboxyporphyrin (protoporphyrin) is excreted exclusively in the feces. The physiologically relevant pathway leading to heme is via uroporphyrinogen III, in which the propionyl and acetyl groups are "reversed" compared with the type I pathway, which "dead-ends" with coproporphyrinogen I. The physiologic significance of the type I pathway remains unclear; however, coproporphyrin I is elevated in hepatobiliary diseases.

PORPHYRIAS

The porphyrias have been classified in the literature in several different ways. Most commonly, porphyrias are presented in textbooks with specific biochemical reference to the principal enzyme deficiency (e.g., δ-aminolevulinate [ALA] dehydratase deficiency) and the site of the deficiency (e.g., hepatic, erythropoietic, or both). Furthermore, the temporal pattern of appearance of overt clinical signs (acute vs chronic) and the primary presentation of symptoms (neuropathic, dermatopathic, or mixed) are valid classifications that arrange porphyrias according to symptomatology. It is useful also to organize porphyrias according to etiology (hereditary vs acquired or toxicant-induced). This review will focus on only those porphyrinurias associated with toxic chemical or heavy metal exposures.

PORPHYRINOPATHIES

Inhibition of an enzyme for heme biosynthesis can result in the inappropriate accumulation of that enzyme's substrate. The more severe the enzyme's inhibition becomes, the greater the tissue accumulation of porphyrins, which sometimes becomes severe enough to cause clinical porphyria.

TABLE 29-1 **Enzymatic Defects of the Common Porphyrias**

ENZYMATIC DEFECT	PORPHYRIA
δ-Aminolevulinic acid (ALA) synthetase	Aminolevulinic aciduria (porphyrinogen precursor)
ALA dehydratase	Plumboporphyria
Porphobilinogen deaminase	Acute intermittent porphyria
Uroporphyrinogen cosynthetase	Congenital erythropoietic porphyria
Uroporphyrinogen decarboxylase	Porphyria cutanea tarda and hepatoerythropoietic porphyria
Coproporphyrinogen oxidase	Hereditary coproporphyria
Protoporphyrinogen oxidase	Variegate porphyria
Ferrochelatase	Protoporphyria

One class of toxic chemicals capable of subtle yet insidious health effects that may mimic other disorders, especially in children, is the heavy metals. Lead, mercury, arsenic, aluminum, and cadmium are well-documented examples. Long-term exposure to these metals often results in organ-specific accumulation that compromises target organ physiology. Similarly, long-term exposure to organic chemicals such as herbicides, pesticides, and industrial and manufacturing by-products can have a deleterious effect on the body's biochemistry that results in the decline of cellular function.[4] Whatever the cause, porphyrins induce oxidative cellular damage when they accumulate.

Clinical Applications

The effect of chemicals on the porphyrin pathway has been the subject of many scientific reports. Lead, mercury, or arsenic toxicity induces porphyrinuria,[7] as do polychlorinated phenyls (e.g., dioxin, polychlorinated biphenyls)[8] and many drugs[9] (Table 29-2). In long-term cultures of adult rat hepatocytes, exposure to submicromolar concentrations of lead increased porphyrin excretion after a delay of 15 to 22 days.[10] A study of practicing dentists reported correlations between elevations of urinary 5-carboxyporphyrin, precoproporphyrin, and coproporphyrin, and behavioral changes that were related to urinary excretion of mercury.[11,12] Together, elevations of these porphyrins served as biomarkers of mercury toxicity.

Upregulation of the heme biosynthetic pathway, with the concomitant increase in ALA, is another mechanism by which porphyria can be precipitated. Increased ALA production is usually a normal physiologic response to provide enough of this preporphyrin precursor to meet the body's demand for heme. However, overproduction of ALA can overwhelm even a normally functioning heme biosynthetic pathway, resulting in the inappropriate accumulation of ALA or the porphyrins.[6] Active porphyria commonly occurs when overproduction of ALA coincides with inhibition of one or more of the porphyrinogenic enzymes. Often porphyria is the result of a chemical insult to a porphyrinogenic enzyme combined with an external stressor that provokes dysregulation of the heme biosynthetic pathway. It is estimated that among patients with a porphyrinogenic enzyme deficiency, as many as 90% are healthy throughout adulthood, until porphyria is triggered midlife

TABLE 29-2 **Interpretation of Abnormal Urinary Porphyrin Test Results: Relationship to Heme Pathway Defects and Possible Causes (with Emphasis on Toxic Metals)**

ABNORMAL TEST RESULT*	HEME PATHWAY ENZYME AFFECTED	POSSIBLE ENVIRONMENTAL CAUSE†
Uroporphyrin and 7-carboxyporphyrin (sometimes)	Uroporphyrinogen decarboxylase	Arsenic[2] or certain organic chemicals
5-Carboxyporphyrin and coproporphyrin	Uroporphyrinogen decarboxylase	Mercury[6]
6-Carboxyporphyrin (sometimes)	Coproporphyrinogen oxidase	Certain organic chemicals
Precoproporphyrin‡ (almost always accompanied by elevated coproporphyin III)	Uroporphyrinogen decarboxylase (possibly)	Mercury[6]
Coproporphyrin III, coproporphyrin I (sometimes)	Coproporphyrinogen oxidase	Lead or mercury[2] Certain organic chemicals
Coproporphyrin I/III ratio >1	Hepatobiliary dysfunction[4] Porphobilinogen deaminase	Arsenic

*Reference ranges vary depending on the laboratory doing the analysis. The reference range for the particular laboratory conducting the analysis should be used. Inherited disorders in the enzymes of heme biosynthesis are relatively rare, but such a possibility should be considered if urinary porphyrins are greatly elevated. A specialist in inherited disorders should be consulted if such a disorder is suspected.

†When urinary porphyrin results are being evaluated to arrive at a diagnosis of metal or chemical toxicity, the following should be ruled out: use of ethanol, estrogens, oral contraceptives, antibiotics, sedatives, analgesics, dietary brewer's yeast; also pregnancy, liver disease, malignancies, and hematologic diseases such as pernicious or iron deficiency anemias.

‡The detection of precoproporphyrin is specifically diagnostic for mercury toxicity.[6]

by toxic chemicals or drugs, an acute illness or worsening chronic condition, or a major dietary change (Table 29-2).[11]

CONCLUSION

Use of porphyrin measurements as biomarkers of chemical toxicity is reasonable in combination with other laboratory tests of toxicant concentrations in body fluids or hair. The clinician should realize that many conditions unrelated to primary or toxicant-induced porphyria can cause porphyrinuria.[13] When considering a urinary porphyrin result, the clinician should be mindful that the distribution of normal urinary porphyrin values, representing healthy individuals, overlaps significantly with values representing those who have had porphyria at one time or another.

Any patients in whom a urinary porphyrins test result is positive should receive more specific testing for a differential diagnosis. Tests that assay toxic metals directly in biologic samples (e.g., blood, urine, and hair) are essential for confirming whether the toxicity symptoms are caused by a metal. Identification of toxic organic chemicals by laboratory methods is also possible. Profiles are available for measuring series of volatile solvents, polychlorinated biphenyls, and chlorinated pesticides in blood or phthalates and parabens in urine. Ruling out porphyria as the primary cause of porphyria-like symptoms requires tests for porphyrinogenic enzyme activities (e.g., uroporphyrinogen decarboxylase), as well as tests for blood, fecal, and urine porphobilinogen and ALA.

Procedure, *238*
Method, *238*
Reagents, *238*
Results, *238*
Interpretation, *239*
Conclusion, *239*

INTRODUCTION

The essential amino acid tryptophan is converted to indole by intestinal bacterial cleavage of the tryptophan side chain. After absorption, indole is converted to 3-hydroxy indole (indoxyl or indican) in the liver, where it is conjugated with potassium sulfate or glucuronic acid. It is then transported by the blood to the kidneys for excretion. Increased urinary excretion of indican can be an indicator of gastrointestinal bacterial overgrowth and dysbiosis.

CLINICAL APPLICATION

Because most of the endogenous indoles have a side chain that prevents cleavage and are instead metabolized to skatole, the production of indicans (indoxyl potassium sulfate and indoxyl glucuronate) reflects bacterial activity in the small and large intestines. Box 30-1 lists conditions in which increased levels are found.[1–4] Elevations of indicans are considered an indicator of gastrointestinal dysfunction and overgrowth of anaerobic bacteria (dysbiosis). The indican test can be used to monitor the efficacy of treatment of gastrointestinal dysbiosis.

Procedure

Detection of indican depends on its decomposition to indoxyl and subsequent oxidation to indigo blue. It is then concentrated in a layer of chloroform for easier measurement.

Method

1. Place 5 milliliters of fresh urine in a test tube.
2. Add 5 milliliters of Obermeyer reagent under a hood to exhaust vapors, and cork securely.
3. Invert several times to mix.
4. Add 2 milliliters of chloroform, cork securely, and invert several times.
5. Allow the chloroform to settle, and then observe.
6. The results are then graded according to the color present in the chloroform layer.

Reagents

- Obermeyer reagent is prepared by dissolving 0.8 grams ferric chloride in 100 milliliters concentrated hydrochloric acide (*caution:* caustic).
- Chloroform (*caution:* volatile and toxic; keep tightly capped).

Results

- Urine color: 0 (negative)
- Light blue: +1
- Blue: +2
- Violet: +3
- Jet black: +4

BOX 30-1 Conditions Associated with Elevations of Urinary Indican[1-4]

- Irritable bowel syndrome
- Small intestinal bowel overgrowth
- Inflammatory bowel disease
- Celiac disease
- Hypochlorhydria
- Gastric ulcer
- Biliary and intestinal obstruction
- Jejunal diverticulosis
- Scleroderma
- Postgastrectomy
- Hartnup disease
- Pancreatic insufficiency
- Diminished peristalsis
- Blue diaper syndrome

INTERPRETATION

A positive result may indicate one of several underlying disorders, any of which can lead to bacterial dysbiosis and/or overgrowth, including hypochlorhydria, maldigestion, pancreatic insufficiency, malabsorption of protein, and excessive dietary protein intake (see Box 30-1). Occasionally a positive test can be caused by increased dietary protein prior to testing, which can be prevented by the institution of a moderate protein diet for 2 days before testing.

False-negative results occur when formalin, methenamine, or sulfasalazine (Azulfidine) is present.[2] Indigo red may occasionally form from slow oxidation. The presence of iodine, salicyluric acid, methylene blue, or thymol causes a violet color that can be removed with the addition of a crystal of sodium thiosulfate. Bile pigments can interfere with the reaction, but can be removed by shaking the urine with barium chloride and filtering.

CONCLUSION

This simple in-office diagnostic test can be used to determine gastrointestinal dysfunction or dysbiosis. A positive test can indicate the need for additional testing for gastrointestinal pathogens or altered GI function. The test for urine indicant can be a clinically useful tool for identifying and treating dysbiosis and optimizing GI health. A limitation of this test arises from the caustic nature of the test reagents, which require a hood to exhaust fumes and care to avoid skin contact.

This section presents a historic, scientific, and practical review of the schools of thought and modalities of natural medicine. We have compiled the work of experts in their fields into what we hope the reader will find a concise, yet useful, description of these practices and modalities. Because of the clinically oriented and alternative nature of these disciplines, the scientific evaluation of their theories and efficacy has been limited in the past. Happily, published research in natural medicine has increased dramatically since *A Textbook of Natural Medicine* was first published in 1985.

Although this textbook is strongly oriented to the scientific method and the use of the peer-review literature for documentation of the efficacy of a therapy, these modalities' widespread clinical use and long history of patient satisfaction demand that they be given a place here even though the mechanisms of action of several have yet to be elicited.

INTRODUCTION

Acupuncture is arguably the most recognizable and widely practiced complementary and alternative medicine (CAM) therapy in the world today.[1] Public acceptance and utilization steadily increased across the globe between 1980 and 2011. In America, where the growth of acupuncture has been most dramatic (outside of China) during these years, we have seen the numbers of licensed, mainly nonphysician practitioners expand rapidly. In Washington State, for example, the number of acupuncture licensees jumped by 227% during the 10 years from 1997 to 2007, the most of any of the CAM professions, including chiropractic. The same report showed the growth of chiropractic licenses was only 14%, whereas that of physicians was 34%. Naturopathic physician licenses also increased considerably, by 134%.[2]

There are several key organizations leading the growth of the acupuncture profession in America as of late 2010:

- NCCAOM: National Certification Commission for Acupuncture and Oriental Medicine
- AAAOM: American Association of Acupuncture and Oriental Medicine
- CCAOM: Council of Colleges of Acupuncture and Oriental Medicine
- ACAOM: Accreditation Commission for Acupuncture and Oriental Medicine

These organizations were formed during 1981 and 1982. The NCCAOM was formed to provide testing for the certification of acupuncturists across America. "The mission of the NCCAOM is to establish, assess, and promote recognized standards of competence and safety in acupuncture and Oriental medicine for the protection and benefit of the public."[3]

The ACAOM was formed to provide accreditation to schools and colleges developing programs of study for the training of acupuncturists. "ACAOM's primary purposes are to establish comprehensive educational and institutional requirements for acupuncture and Oriental medicine programs, and to accredit programs and institutions that meet these requirements."[4]

The CCAOM was formed "to advance acupuncture and Oriental medicine by promoting educational excellence within the field. The philosophy of the Council is based on respect for the broad range of traditions of acupuncture and Oriental medicine and a commitment to academic freedom."[5]

The AAAOM was the first major professional organization to lead this budding profession. "The AAAOM is the national professional association promoting and advancing high ethical, educational, and professional standards in the practice of acupuncture and Oriental medicine (AOM) in the U.S. The AAAOM mission statement is: To promote excellence and integrity in the professional practice of acupuncture and Oriental medicine in order to enhance public health and well-being."[6]

As a result of the ongoing work of these organizations, the following milestones were achieved as of late 2010:

- Licensure: 44 states plus Washington, DC[7]
- Licensed acupuncturists: estimated 25,000–30,000[8]
- CCAOM Schools and Branches: 60[9]
- NCCAOM Diplomates since 1982: 22,000[10]
- Students in acupuncture schools: 8000[11]

There are several types of providers that receive training in acupuncture as noted in Box 31-1.[12] On occasion, professionals such as medical doctors, naturopathic physicians, and chiropractors undergo extensive training in acupuncture, but it is more common to receive professional specific training composed of far fewer hours.

BOX 31-1 Acupuncture Training Comparisons

Acupuncture Training	Physician Training	Other
• Licensed Acupuncturist (LAc standard) • 3-4 Years Professional, post bachelors standard • 1500 to 2000 hours acupuncture specific	• MD, DO, ND, DC • 300 hours or less, acupuncture specific • 100 hours for chiropractic add on	• Physical therapist • 40-50 hours of "dry needling" • National Acupuncture Detox Association detoxification technicians • 100 hours or less

TABLE 31-1 China Acupuncture Statistics

CHINESE ACUPUNCTURE AND TCM STATISTICS	
TCM doctors	218,044
TCM clinics	35,477
TCM hospitals	2688
Beds	350,257
Acupuncture hospitals	6
TCM doctors per 10,000 population	2.69 (0.69-0.83 USA)
Chinese investment in TCM	1.7 billion yuan

TCM, Traditional Chinese Medicine.

For perspective and comparative purposes, Table 31-1 provides numbers from mainland China showing traditional Chinese medicine (TCM) statistics for the years 2007 and 2008. Acupuncture is considered a key component of the practice of "modern" TCM, along with herbal medicine, massage, nutrition, qigong, and health promotion.[13–16]

The World Health Organization stated in 2001 that "Chinese Medicine, particularly acupuncture, is the most widely used traditional medicine. It is practiced in every region of the world." Although this statement has not been revised as of 2011, there is every reason to believe that this remains true.[17]

Western acupuncture terminology is evolving. Even the term "acupuncture" is considered ambiguous and deserves qualifiers to better guide consumers and professionals engaged in the practice. The following statement reflects this opinion: "The term 'acupuncture' in and of itself is ambiguous. It has been used to refer to either a specific procedure involving acupuncture needling or a multicomponent treatment that also involves history taking, physical examination, diagnosis, and education. In some cases, nonneedling procedures (e.g., laser, TENS) conducted at acupuncture points are also referred to as acupuncture."[18]

Even the acupuncture credential that this author states in *Textbook of Natural Medicine* reflects the changing practice landscape. In 2010, the legislature of Washington State approved major scope changes and terminology concerning the licensure of acupuncturists. The widely excepted term L.Ac. (licensed acupuncturist) in the United States was removed and replaced with the term East Asian Medical Practitioner (EAMP) to reflect a long-standing opinion within the field of acupuncture practice that acupuncture is an ambiguous term "in and of itself" and is a "multicomponent treatment."[19]

In the state of California, acupuncture licensure was also expanded to reflect this trend. "The theory and practice of acupuncture is based on Asian medicine (also known as traditional, classical Chinese or Oriental medicine), a comprehensive natural health care system that has been in use in Asian countries for thousands of years to preserve health and diagnose, treat, and prevent illness."[20]

Contrasting biomedicine and Chinese Medicine in his 2002 article in the *Annals of Internal Medicine*, Kaptchuk stated that "Chinese medicine relies on the veracity of the senses, the person-centered experience either as reported by the patient or perceived by an observant practitioner."[21]

The definition of acupuncture is not as firmly agreed upon as one would imagine. Acupuncture as simply "a Chinese medical practice or procedure that treats illness or provides local anesthesia by the insertion of needles at specified sites of the body" is an oversimplification of a practice that has evolved over many generations with many variations and can describe an entire field of medical practice rooted in ancient classics.[22] A more comprehensive definition agreed upon by the greater acupuncture community helps in the transmission of acupuncture principles to the world at large, aiding in the support of new research and advances in the field.

As for historical perspective on the actual term, according to George Lewith's writings, "acupuncture, or needle puncture, is a European term invented by Willem Ten Rhyne, a Dutch physician who visited Nagasaki in Japan in the early part of the seventeenth century. The Chinese describe acupuncture by the character 'Chen,' which literally means 'to prick with a needle,' a graphic description of this therapeutic technique."[23]

The California Acupuncture Board, which licenses more than 8500 acupuncturists, states the following:

> *Acupuncture means the stimulation of a certain point or points on or near the surface of the body by the insertion of needles to prevent or modify the perception of pain or to normalize physiological functions, including pain control, for the treatment of certain diseases or dysfunctions of the body and includes the techniques of electroacupuncture, cupping, and moxibustion.*[24]

The practice of acupuncture, according to Business and Professions Code section 4937 (b) of California, is as follows: "to perform or prescribe the use of oriental massage, acupressure, breathing techniques, exercise, or nutrition, including the incorporation of drugless substances and herbs as dietary supplements to promote health."[25]

In November 1997, the National Institutes of Health (NIH) convened a consensus development conference on the subject of acupuncture. After discussion among a board of experts, the following working definition was included in the NIH Consensus Statement:

> *Acupuncture describes a family of procedures involving stimulation of anatomical locations on the skin by a variety of techniques. There are a variety of approaches to diagnosis and treatment in American acupuncture, which incorporates medical traditions from China, Japan, Korea, and other countries. The most studied mechanism of stimulation of acupuncture points employs penetration of the skin by thin, solid, metallic needles, which are manipulated manually or by electrical stimulation.*[26]

The NIH conference has had a lasting positive impact on the growth of acupuncture in America and probably in the world. The definitions and recommendations for further research have sparked wider acceptance within the medical profession. No longer is acupuncture merely a novelty practice from the East.

HISTORY

The historical timeline of Chinese medicine spills over thousands of years to the present. This vast expanse of history can only be captured in mere snapshots of traditional practice, some of it legend, some of it practiced to this day. A rich folk medicine survives in the dozens of minority cultures making up the whole of China. Some attempt exists today to revive an element of these practices. Chinese medicine begins with a legend about the infamous Yellow Emperor, Huangdi (approximately 2698-2598 BC).[27,28] The so-called "Father of Chinese Medicine," Huangdi reigned over a vast Chinese empire. The core of Chinese medicine, acupuncture, and pharmaceutics is traced to the greatest and oldest medical text on earth, the Yellow Emperor's *Canon of Medicine.* Unknown medical scholars of the Warring States period (221 BC and 220 AD) wrote the text that is fixed to Huangdi's name.[29]

Nevertheless, this book is attributed to the reign of Huangdi and is said to highlight questions and answers among the emperor and his ministers, particularly a physician named Qi Bo. Huangdi discoursed on medicine, health, lifestyle, nutrition, and religious tenets of the times. He is ascribed such a high place in Chinese history that many Chinese people consider themselves descendants. Huangdi is viewed as the "symbol of vital spirit of Chinese civilization."[30] Probably the most important text in the history of Chinese medicine, often overshadowed by the "reputation and authority of the original classic," the *Huangdi Nei Jing,* was the *Nan Jing (The Classic of Difficult Issues),* thought to have been compiled around the first or second century AD. According to Unschuld,[31] the *Nan Jing* was "a significant and innovative work that was the apex and conclusion of the developmental phase of the conceptual system unknown as the medicine of systematic correspondence." He went on to describe the importance of the *Nan Jing,* saying "the Nan-ching (jing in pinyin romanization) is comprehensive . . . discusses the origins and the nature of illness; outlines a system of therapeutic needling; and develops—in great detail—an innovative approach to diagnosis." The *Nei Jing* predates the historically available writings of ancient China and delves strongly into "demonological medicine and religious healing," whereas the *Nan Jing* is homogeneous and highly systemized, basically intact, and well focused.[32]

In terms of acupuncture, Unshuld[33] cites no "reliable" references before 90 BC appearing in Chinese literature. Ancient works as a whole were written on bamboo strips and silk. These went through countless hands and copies, creating a body of written work that contained numerous errors and omissions. It was not until 26 BC that the Chinese government organized medical officials to collate and revise the royal collection of medical works preserved at the Mifu Natnal Royal Library.[34] The earliest recorded physician reputed to be versed in pulse-taking and acupuncture was Bian Que (approximately 500 BC). Several medical works ascribed to him have been lost.[35] Su Ma Qian, historian of the Han dynasty (206 BC-220 AD), wrote a chapter on the biography of Bian Que in the *Historical Note* about 100 BC. This was the first reliable reference documenting acupuncture and moxibustion in Chinese. He told many stories of Que's ability to treat with acupuncture. Zhang Ji (150-219 AD), referred to as the sage of Chinese medicine, authored the classic work *Shanghanlun.* Statues of the legendary Zhong Ji are common on many of the TCM college campuses in mainland China today. Another of the famous ancient masters of Chinese medicine was Hua Tuo (?-208 AD), a surgeon and practitioner of an eclectic range of therapies, including acupuncture and hydrotherapy, and an originator of the therapeutic exercises called the "five animals."[36]

Huangfu Mi (214-282 AD), a famous acupuncturist, compiled *Zhen Jiu Jia Yi Jing (A Classic of Acupuncture and Moxibustion),* the first monograph on acupuncture in history, around 282 AD. These 12 volumes covered all aspects of acupuncture practice and theory and are considered a monumental work.[37]

The first usage of the English term "acupuncture," meaning needle puncture, is attributed to a Dutch physician, Rhyne, who visited Japan sometime in early seventeenth century.[38] Dr. Berlioz of the Paris Medical School was attributed with the first recorded use of acupuncture in the West. John Churchill, in 1821, was the first British acupuncturist to publish works highlighting treatment of tympany and rheumatism. Acupuncture is also mentioned in *Lancet's* first edition in 1823. Dr. Elliotson published results of 42 cases of acupuncture treatment of rheumatism, concluding that acupuncture was effective as a treatment.[39]

In 1825, Franklin Bache, MD (Benjamin Franklin's great grandson) published an article on acupuncture in the *North American Medical and Surgical Journal*, detailing his clinical trials utilizing acupuncture on prisoners with various conditions. Michael Devitt wrote a wonderful account about this early pioneer of acupuncture in the *American Acupuncturist*.[40]

As noted earlier, in 1849, the Gold Rush in California helped to spark a large immigration of mostly male Chinese people into Western America. Heading for "Gold Mountain," they brought all elements of their culture, including their traditional medicine with its acupuncture and Chinese herbs. Writing in his book, *Chinese Medicine on the Golden Mountain,* Paul Buell stated the following: "[There] was an acute shortage of any form of medical care in Western America where most Chinese settled. Well practiced Chinese medicine was often superior to contemporary Western practice. Western medicine did not gain any real advantage over well practiced Chinese medicine until the coming of any 'wonder drugs' in the 1930s, and in some respects, as in many chronic ailments, (traditional) Chinese medicine is still superior."[41]

In an interesting mention of acupuncture in 1892, William Osler wrote, in his *Principles and Practice of Medicine,* about the use of acupuncture in the treatment of sciatica.[42] There would be few other mentions of the subject in American medical literature for many years to come.

FUNDAMENTALS OF ACUPUNCTURE

Acupuncture is a technique involving the insertion of fine needles into the skin at select points or points of tenderness. As discussed earlier, the theory, or acuology, that surrounds the practice dates back as many as 4000 to 5000 years. Possible historical links to India and even other areas have been suggested. For many contemporary practitioners, their practices of acupuncture are defined by the theory of the fundamental principles: five elements (e.g., phases, movements), Yin, Yang, Qi, and Zang Fu. For still others, these ancient theories remain just that—ancient and removed from modern science—and they practice acupuncture solely on the basis of recent theories of mechanism and anecdotal evidence.[29,43]

Yin and Yang, on which all diagnosis and treatment in TCM is based, is the central theory in the practice of acupuncture. In perfect balance, in optimal health, Yin and Yang are harmonious, the ebb and flow of the tides, day and night, male and female. The theory, when translated, can be set in quite poetic terms. A deficiency of liver and kidney Yin, for example, might result in clinical symptoms

such as dizziness, vertigo, insomnia, dry throat, and lumbago, whereas a deficiency of spleen and kidney Yang may manifest clinically as cold limbs, lumbago, diarrhea, and scanty urine. Excess is usually seen as a relative state due to the deficiency of the other, as in deficient Yin resulting in an apparent excess of Yang.

Qi

Qi is the energy and potential energy that courses throughout the organism and defines what we call life. The lack of proper Qi flow in the system results in numerous maladies. Qi stagnation often manifests as pain. Rebellious Qi manifests as belching, burping, and vomiting, a reversal of the normal downward movement of Qi digestively. Potential Qi is that energy that is bound up in inanimate objects, such as rocks and furniture, that can become more active if expressed or liberated. Then there is the Qi that weaves through space, connecting us to the web of the universe—a concept that begins to sound like theories in quantum physics.

Zang Fu

The Zang Fu are the Chinese organs, five solid Yin and six hollow Yang. In the West, English names are used for the organs—liver, heart, spleen, kidneys, and lungs—but depending solely on the Western name without a thorough understanding of the traditional Chinese meaning leads to much confusion clinically. A complete and clinically sound synthesis of the Western biomedical understanding with the traditional Chinese understanding has not occurred to date. For example, the liver as known in the West is defined according to its anatomical structure and function (i.e., it is a large glandular organ that secretes bile and metabolizes blood-borne compounds). The Chinese gan (liver) stores blood and Qi, and is responsible for the smooth transmission of Qi and blood throughout the body. Moreover, it has a chief role in emotions; an unbalanced gan (liver) results in anger, high blood pressure, and a general state of agitation. The liver in the Chinese sense is much more a functional system with many body-wide interactions. The hollow organs are the gallbladder, large and small intestines, "triple burner," urinary bladder, and stomach. The triple burner is a good example of how different the Western and Chinese views are, because this has no meaning in the West. In the Zang Fu system, the triple burner corresponds to the thoracic and abdominal regions, including all of the organs within these regions. It has a specific function that distinguishes it as a Fu organ, namely, to transport water.

The Five Elements

The five elements (also called the five phases or in Chinese, wu xing) are fire, metal, wood, earth, and water. The correspondences among these elements have led to a method of diagnosing and treating patients.

In the West, a school of thought following the teachings of Dr. Worsley in England evolved and grew into a worldwide system of schools and practitioners associated with the so-called law of five elements. There is a stark contrast between this system of acupuncture practice and the TCM systems.

Points and Meridians

The other key aspect of the fundamentals of acupuncture is, of course, the theory of the channels. There are the basic 365 mapped acupuncture points along the 12 major and 8 extra channels, as well as more than 1000 extra points and special use points, including the microsystems, such as the hand, ear, and scalp, all with specialized functions. The so-called ashi points, or pain points, can literally be located anywhere on the body where there is a pain locus. Qi and blood flow throughout the channels, and this is where the proper manipulation of the needle is critical in properly moving this flow.

ACUPUNCTURE SCOPE OF PRACTICE

Similar to the challenges in universal acceptance of an exact definition of the term acupuncture, the clinical practice of acupuncture also varies across the world and in different American jurisdictions. There are 45 American State and District of Columbia acupuncture practice acts as of early 2011. Although there is a core of therapeutic acceptance from state to state, there are wide variations in expanded scopes. Although most states use the designation "L.Ac." a few have begun to use other credentials such as "Doctor of Acupuncture" in Rhode Island and "Doctor of Oriental Medicine" in a few other states.[44]

New Mexico is a good example of perhaps the broadest acupuncture scope in America. The practice of "Oriental Medicine" includes homeopathy, prescriptive drug authority (with expanded practice certification), laser therapy, injection, and IV therapy, all within its Doctor of Oriental Medicine (DOM).[45]

Although California law has in many ways set the pace for the profession through the years with a scope that now defines acupuncturists as primary health care professionals with a practice inclusive of Asian massage, acupuncture, herbal medicine, exercises, breathing techniques, and dietary supplements, among others, it is the Washington State law that forged entirely new ground for acupuncturists in America.

The stage was set for the renaming and overhaul of the state acupuncture law for a number of reasons, including the strong desire by a Korean Washington State legislator to rid the Western world of the term "Oriental," an upcoming sunset review, and several confusing and deficient parts of current acupuncture law. What resulted was the insertion of the term Asian in place of Oriental in the Washington State acupuncture regulations. "East Asian medicine means a health care service utilizing East Asian medicine diagnosis and treatment to promote health and treat organic or functional disorders and includes the following: Acupuncture (or lancets), Electrical, mechanical, magnetic devices, moxibustion, acupressure, cupping, dermal friction technique, infra-red, sonopuncture, laserpuncture, point injection therapy (aquapuncture), dietary advice (including recommendation and sale of herbs, vitamins, minerals), breathing, relaxation and East Asian exercise, Qi Gong, East Asian massage and Tui na, and superficial heat and cold therapies."

Acupuncturists in the State of Washington now can use the credential EAMP.[46]

ACUPUNCTURE SAFETY

Acupuncture therapy is a safe and relatively pain-free procedure. There are many forms and styles of acupuncture therapy practiced; some have a reputation for potentially being more painful at times, but generally the procedure is painless. Millions of treatments have been performed by licensed acupuncturists in America with very little reporting of adverse effects. Most licensed acupuncturists in America have taken "clean needle" training as part of their basic acupuncture training. For the past 15 years, it has been the standard of care in acupuncture practice that single use disposable needles are used in all treatments.

In the past year there has been renewed discussion about the safety of acupuncture sparked by a *British Medical Journal* (*BMJ*) editorial piece that put a cautionary spin on the view that acupuncture needling is entirely safe, or at least has virtually no side effects.

The article, "Acupuncture Transmitted Infections," although highlighting the skin infection risk of acupuncture needling, also identified only "more than 50 cases" to date (2010) worldwide. Nevertheless, the authors' main opinion stated that these type of infections were underreported.[47] An older report also published in the *BMJ* by Vincent seems appropriately titled, "The Safety of Acupuncture; Acupuncture Is Safe in the Hands of Competent Practitioners." Vincent stated, "The conclusion that acupuncture is a very safe intervention in the hands of a competent practitioner seems justified on the evidence available."[48] A large review study published in 2008 focused on acupuncture safety and efficacy in pediatrics. The authors "found evidence of some efficacy and low risk associated with acupuncture in pediatrics." They stated some caution as well, noting "the safety of acupuncture is a serious concern, particularly in pediatrics. Because acupuncture's mechanism is not known, the use of needles in children becomes questionable." They also stated, "nevertheless, it seems acupuncture is a safe complementary/alternative medicine modality for pediatric patients on the basis of the data we reviewed."[49]

The NCCAOM and the AAAOM jointly authored a response to the *BMJ* editorial, stating that "the article neglected to mention that the incident of infections is drastically reduced when a consumer seeks a qualified practitioner who has met the rigorous standards of the NCCAOM certification which includes passing of the Council of Colleges of Acupuncture and Oriental Medicine (CCAOM's) clean needle technique course, a prerequisite to becoming an NCCAOM certified practitioner."[50] They stated in another article that, "while acupuncture is a highly effective and valuable form of healthcare, it is not an entirely risk-free medical procedure, and should be administered by practitioners with the proper training who follow accepted guidelines of practice."[51]

EVIDENCE-BASED ACUPUNCTURE

The defining moment for acupuncture research came with the conclusion of the NIH Consensus Conference in 1997. For the first time, a Western panel of medical experts gathered to review, critique, and set guidelines for the use of acupuncture in the medical field in America. Before this conference, research in acupuncture was acknowledged by some Western doctors but largely dismissed. The view of Asian studies and of studies from other countries in general did not make an impact on the American radar. The conference helped focus the attention, collect what research had been completed to date, and concluded that there was merit in the use of acupuncture for certain conditions and, most importantly, that there was a real need and demand that acupuncture be better studied and used. Acupuncture was finally "on the map" in the West.[52]

Progress was made in the 10 years after the NIH conference, as was detailed by the 2007 Society for Acupuncture Research (SAR) International Symposium.[53] The symposium detailed a number of important research conclusions, highlighting growing evidence for the effectiveness for chronic pain while detailing the issues concerning sham acupuncture in trials, as well as a number of basic science trials demonstrating the physiologic effects of needling. Paradoxes in acupuncture research are the focus of increased discussion and remain an issue important in 2011.

Box 31-2 highlights the state of evidence-based acupuncture as of late 2010.[54-57] These conditions have been well researched, and the evidence is there for their inclusion in the list. For many acupuncturists who still tout the dated WHO list of conditions for application to acupuncture, this list would appear inadequate and incomplete. To the medical skeptics who doubt the blogosphere and appear 100% opposed to anything CAM, this list is probably highly suspect. This is the state of CAM in 2011. Somewhere between the true believers and the skeptics lies the truth. The research community that is honestly trying to attain that truth for the betterment of science and human health deserves respect for their efforts.

Western medical practice has grown within a system of great scrutiny and self-analysis. A massive research culture spins off studies by the thousands. The double-blinded, placebo-controlled trial has become the hallmark of the "appropriately conducted research trial." Acupuncture evolved in a completely different culture, that of China, where, ironically, as we were "discovering" the Chinese traditional system of acupuncture, not so many years ago, the Chinese began a wholesale discovery of traditional Western medicine. Acupuncture and all that is TCM have been extensively researched in China. What is the quality of that research? Does it meet the scrutiny of Western "gold standard" research?

Large research academies, the largest being the China Academy of Traditional Chinese Medicine in Beijing, and various universities and schools of TCM, have created a huge research culture in China since the 1970s. Although there is considerable emphasis on herbal research, there is still quite a lot of research examining the other areas of TCM, including acupuncture. What does this Chinese research culture mean for Western medicine? This is a big question that is being sorted out in numerous ways today. The issues still at hand regarding Chinese research are the following:

- Too few numbers of English-translated TCM journals[58]
- Lack of studies using "approved" Western research standards
- Terminology issues
- Major design issues
- Inflated outcome assumptions
- Lack of Western acceptance of Chinese studies

BOX 31-2 Evidence-Based Acupuncture: Medically Necessary Indications

- Chronic pain
- Low back pain
- Chronic neck pain
- Osteoarthritis
- Postoperative pain
- Fibromyalgia
- Postoperative nausea/vomiting
- Chemo-induced nausea
- Dental pain
- Endoscopy pain

INTRODUCTION

Ayurveda is one of the most ancient systems of medicine known today. The origins of this science of life (*Ayu*—life and *Veda*—knowledge), although difficult to pinpoint, have been placed by scholars of ancient Indian Ayurvedic literature somewhere around 6000 BC.[1]

Ayurveda is a holistic science of health and a balance in lifestyle. Disease is seen as an imbalance, and its treatment involves diverse strategies to restore optimal function and balance. Using dietary alterations, yoga, and exercise, along with elaborate surgical techniques and complex, integrated herbal formulas, the Ayurvedic physician treats the whole person, removing disease completely by ending the imbalance that created it.

HISTORY

In ancient India, it was custom for a teacher's instruction to be recorded by his students, who would eventually repeat the same information orally to their own disciples. Thus, according to the different interpretations given by various disciples of Ayurveda, a number of treatises were written. Although specific instructions differed, the basic principles remained the same.

Ayurvedic teachings were orally transmitted for thousands of years and then written down in melodious Sanskrit poetry. The contents of a number of Sanskrit verses, or *shlokas*, although written many centuries ago, still sound a note of familiarity in today's scientific environment. Ayurveda, in its first recorded form (*vedas:* the world's oldest literature), is specifically called *Atharveda.*

The Development of Ayurvedic Medicine

Hindu legend holds that, after seeing the suffering of human beings, Lord Brahma, the god of creation, elaborated ways to ease that suffering to Daksha, who, in turn, taught them to the Ashwin twins. Figure 32-1 presents the chronology of Ayurveda's development.

Dhanvantari and Bhardwaj separately developed the surgical and medical aspects of Ayurveda around the ninth century BC. Their students recorded these principles in great detail in compendia that are called *Samhitas.*

The *Sushruta Samhita*, one of the most widely accepted Ayurvedic texts, emphasizes the surgical aspects of therapy. Its author, Sushruta, is considered the father of surgery (particularly of plastic and reconstructive surgery). The medical teachings of Charak were a synthesis of earlier work. His material has become a classic text of the nonsurgical medical wisdom of Ayurveda. Successive generations have modified his work, the *Samhita.*

THE MAJOR SCHOOLS AND SPECIALTIES

School of Physicians *(Atreya Sampradaya)*

Charak wrote a complete text on Ayurvedic medicine in which he revised the work of Agnivesh. Charak's text described the *Tridosh* physiology *(Vat, Pit,* and *Kaph)*, seven *Dhatus* (tissues), and three *Malas* (excretions). His text covered the pathophysiology and treatment of diseases, human constitution *(Prakriti),* classifications

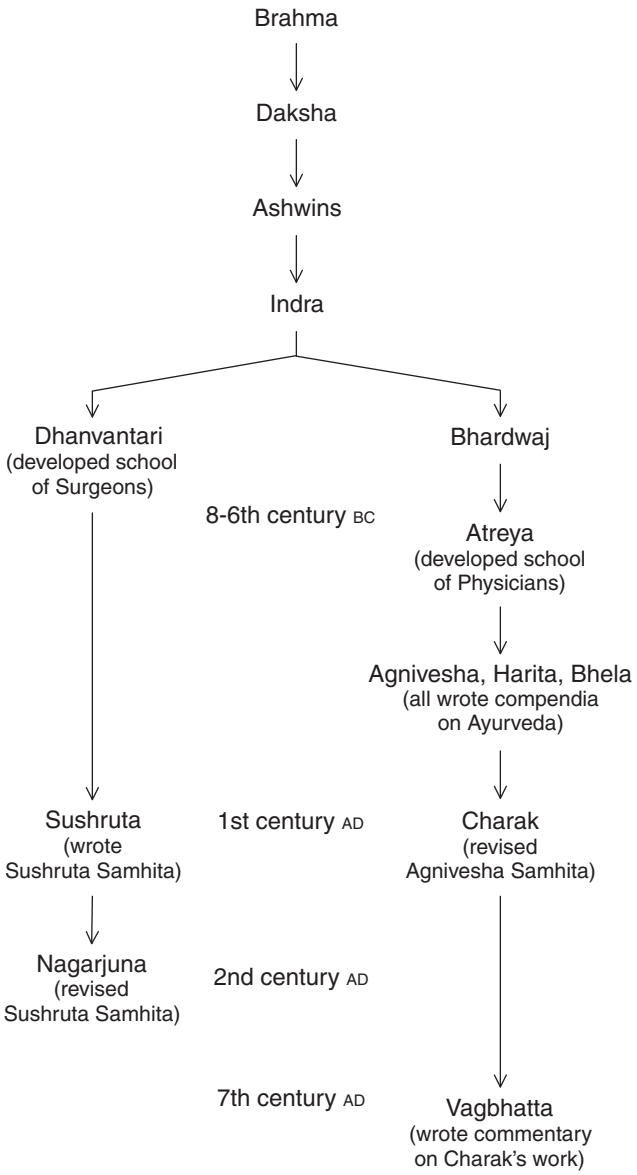

FIGURE 32-1 The chronology of Ayurveda.

and preparations of drugs, diet, "right conduct," medical ethics, and many other aspects of medicine.

School of Surgeons *(Dhanvantari Sampradaya)*

Sushruta wrote the first comprehensive works on surgery. These were later revised by Nagarjuna in the second century AD. The major subjects in his texts were the following:

- Injections
- Preoperative care
- Postoperative care
- Suturing
- Asepsis
- Sterilization
- Operation theaters
- Hospitals

Sushruta described 141 types of instruments and listed 40 types of surgeries and surgical techniques for treating cataracts, hemorrhoids, hernias, and bone problems, for cosmetic and plastic purposes, and for the removal of kidney stones and gallstones.

TABLE 32-1 **Specialties in Ayurveda**

AYURVEDIC NAME	ENGLISH NAME
Shalya Tantra	General surgery
Shalkya	Ophthalmology and otorhinolaryngology
Kaya Chikitsa	Medicine
Bhutvidya	Psychiatry
Kumar-Bhritya	Pediatrics, obstetrics, gynecology
Agada Tantra	Toxicology and jurisprudence
Rasayana	Geriatrics
Vajikaran	Fertility and sterility

Branches of Ayurveda

Ayurveda encompasses eight specialties or branches. They comprise a system developed to prevent and cure disease, as well as achieve and maintain excellent health. Table 32-1 lists the branches.

PHILOSOPHY

Ayurvedic philosophy is based on the Samkhya philosophy of creation. It has influenced major strains of philosophy in both Eastern and Western civilization. The word *Samkhya* is derived from the Sanskrit words *Sat* (truth) and *Khya* (to know). The *Rishi Kapila* (*Rishi* means realized beings or seers of truth) realized the Samkhya philosophy of creation. They perceived the following:

- The close relationship between humans and the universe (that humans are a microcosm, a universe within themselves, whereas the external environment is the macrocosm).
- The source of all existence is cosmic consciousness, manifest as male *(Shiva* or *Purusha)* and female *(Shakti* or *Prakriti)* energy.

Purusha is formless, colorless, and beyond attribute. *Prakriti* has form, color, awareness, and choice. *Prakriti* creates all the forms of the universe and has three attributes *(Gunas): Satva* (essence), *Rajas* (movement), and *Tamas* (inertia). It is also represented by Brahma (the god of creation), *Vishnu* (god of protection), and *Shiva* (god of destruction), which together comprise a cycle active in this universe.

In *Prakriti,* the three attributes are in balance. Whenever this balance is disturbed, they interact to bring about the evolution of the universe, yielding the cosmic vibration of *Aum.* The cosmic intellect (the *Mahad*) manifests itself as ego *(Ahamkar)*, which, through the help of *Satva,* manifests the five senses and five motor organs, which together constitute the "organic universe." Ego further manifests into the five basic elements (space, air, fire, water, and earth), which, under the influence of *Tamas,* create the "inorganic universe."

Satva is a creative potential *(Brahma), Rajas* is a kinetic protective force *(Vishnu),* and *Tamas* is a potentially destructive force *(Mahesh).* These three—*Brahma, Vishnu, and Shiva*—are constantly operating in the universe.

Five Basic Elements and the Universe (Panchbhuta Philosophy)

The *Rishis* perceived that consciousness consists of these five basic elements: ether (space), air, fire, water, and earth. At the beginning of the world, consciousness was without form, existing as the subtle vibration of the cosmic "soundless" sound *Aum.*

TABLE 32-2 **The five elements and the senses**

ELEMENT	SENSE	ORGAN	ACTION	VEHICLE OF ACTION
Ether	Hearing	Ear	Speech	Mouth
Air	Touch	Skin	Holding, giving, receiving	Hand
Fire	Vision	Eye	Walking	Feet
Water	Taste	Tongue	Procreation	Genitals
Earth	Smell	Nose	Excretion	Anus

Within these vibrations appeared the element ether. Ether started to move, creating air. The movement of ether also produced friction and, through friction, generated heat, then fire. From the heat of the fire, ethereal elements dissolved and liquefied into water. Water then solidified to form molecules of earth. Thus, all matter was born from the five elements. These five elements exist in energy forms.

Five Elements and the Senses

The five elements also connect with the five senses: ether—hearing, air—touch, fire—vision, water—taste, and earth—smell, and they are present in certain physiologic functions. Expressing the functions of the sensory organs are five actions (Table 32-2). In this manner, the elements are directly related to humans' abilities both to perceive the external environment in which they live and to respond to it:

- Ether is the medium through which sound travels. The ear is the organ of hearing, expressing its action through the organ of speech, which creates meaningful sound.
- Air is related to skin and the sense of touch. Its organ of action is the hand, which is especially sensitive. The hand performs the actions of holding, giving, and receiving.
- Fire produces light, heat, and color, and is thus related to vision and direction. Its organ is the eye.
- Water relates to the organ of taste. The tongue is also related to the action of the genitals, the penis, and clitoris. In Ayurveda, the penis and clitoris are called the lower tongues. By controlling the upper tongue, one naturally controls the lower tongue.
- The earth element relates to the sense of smell, and the nose is its organ.

PHYSIOLOGY

The five elements manifest within the body as the *Tridosha* (*Dosha* means protective or, when out of balance, disease producing). The *Tridosha* are the three humors, or basic principles, described earlier—*Vat, Pit,* and *Kaph.*

From the bodily combination of ether and air comes the bodily air principle, *Vat Dosha*. Likewise, fire and water combine as *Pit Dosha,* or fire principle, and earth and water produce the *Kaph Dosha,* or water principle.

These three control all biological, psychological, and physiopathologic functions of the body, mind, and consciousness. They produce natural urges and individual tastes in food, flavor, and temperature. They govern the maintenance and destruction of bodily tissue and the elimination of waste products. They also are responsible for psychological phenomena, including the emotions of fear, anger, and greed, as well as the highest order of emotions: understanding, compassion, and love.

BOX 32-1 **Properties of *Dosha***

Vat	***Pit***	***Kaph***
Dry	Oily	Oily
Light	Light	Heavy
Cold	Hot	Cold
Rough	Liquid	Slimy
Subtle	Penetrating	Soft
Mobile	Mobile	Static
Clear		Dense
Dispersing		Slow
Smells sour		

Properties of *Dosha*

Vat, Pit, and *Kaph* control all human biological, psychological, and physiopathologic functions and have subtle properties, as shown in Box 32-1.

The *Doshas* increase by similar properties and are diminished by opposite properties. For example, *Vat* is dry, light, and cold, so any food, medicine, lifestyle, or behavior that increases these qualities increases *Vat* within the body. Conversely, oily, heavy, or hot factors decrease *Vat.*

Functions of *Tridosha*

Each humor has a specific action. *Vat* is the principle of movement and may be called the bodily air principle, as opposed to the environmental air principle. *Vat* is a subtle energy governing all biological movement—breathing, blinking, muscle and joint movement, heartbeat, and all nerve and membrane contractions and expansions. In addition, it controls the psychological functions governing the emotions of fear and anxiety. *Vat* also controls pain, tremors, and spasms. Broadly speaking, the whole nervous system can be labeled as *Vat* function. The large intestine, pelvic cavity, bones, skin, ears, and thighs are the places of *Vat.* Any excess of *Vat* accumulates in these areas.

Pit, or bodily fire, governs digestion, absorption, assimilation, nutrition, temperature, skin color, luster of the eye, intelligence, and understanding. It arouses anger, hate, and jealousy. The small intestine, stomach, blood, sweat glands, fat, eyes, and skin are the places of *Pit;* all metabolism is governed by *Pit.*

Kaph, biological water, is the cement of the body, providing for physical structure. It is responsible for body resistance and biological strength. It lubricates the joints; provides moisture to skin; and promotes wound healing, strength, vigor, and stability. It supports memory, gives energy to the heart and lungs, and maintains immunity. *Kaph* is present within the throat, chest, head, sinuses, nose, mouth, stomach, joints, cytoplasm, plasma, and liquid secretions. Psychologically, *Kaph* governs attachment, greed, longstanding envy, calmness, forgiveness, and love.

A balance of the *Dosha* is necessary for optimal health. Together, they govern all metabolic activities: anabolism *(Kaph),* catabolism *(Vat),* and metabolism *(Pit).*

Individual Psychosomatic Constitutions—*Prakriti*

Prakriti, a Sanskrit word composed of *pra* (before) and *akriti* (creativity), denotes the constitution of each individual as determined at conception. At the time of fertilization, permutations of *Vat, Pit,* and *Kaph* determine the constitution of the new individual,

with maleness or femaleness dominating other traits. These basic traits are also shaped by other important factors, such as diet, lifestyle, behavior, emotions, and seasons.

As illustrated in Box 32-2, up to seven different constitutions can exist depending on the permutation and combination of *Vat, Pit,* and *Kaph. Prakriti* is genetically determined; the basic constitution, the combination of the three humors, remains unchanged throughout an individual's lifetime. The combination can, however, respond to environmental changes.

Life is considered a sacred path in Ayurveda, a ceaseless interaction between the internal *(Tridosha)* environment and the external environment, or the sum of cosmic forces. To counteract external change, an individual may create a balance in the internal forces by altering diet, lifestyle, and behavior. The characteristics of the corresponding psychosomatic constitutions are listed in Table 32-3.

BOX 32-2 The Seven Types of Constitution

- *Vat*
- *Pit*
- *Kaph*
- *Vat-Pit*
- *Pit-Kaph*
- *Kaph-Vat*
- *Vat-Pit-Kaph*

Mental Constitutions

On the mental and astral planes, three *Gunas* (attributes of female energy or *Prakriti*) correspond to the three humors that make up the physical constitution. In the Ayurvedic system, the *Gunas* are *Satva, Rajas,* and *Tamas.* They provide the basis for the distinctions in human temperament and individual differences in psychological and moral dispositions. These attributes are further subdivided, but that is beyond the scope of this chapter.

Satva

This type of mind expresses essence, understanding, purity, clarity, compassion, and love. People of Satvic psyche (*Satva* temperament) have healthy bodies and pure behavior and consciousness. They believe in the existence of God, are religious, and are often holy persons.

Rajas

This type of mind operates on the sensual level. Such persons are interested in business, prosperity, power, prestige, and position. They enjoy wealth, are generally extroverted, and are politically minded.

Tamas

This type is distinguished by its ignorance, inertia, heaviness, and dullness. Tamasic people are lazy, selfish, and destructive by nature. They show little respect to others. All their activities are egocentric. The Satvic person attains self-realization without much effort, whereas those of Rajasic or Tamasic mind have difficulty.

TABLE 32-3 **Psychosomatic constitutions *(Prakriti)***

CHARACTERISTIC	*VAT*	*PIT*	*KAPH*
Body frame	Tall or small, thin, ill-nourished, hard, dry, cold	Medium, many moles, well nourished, pimples, patches of freckles, pigment, tender appearance	Stout, well-nourished, big, oily, greasy, cold, beautiful
Skin	Dry, cracked, tough, broken, brownish, black	Soft, thin, yellow, red, pink	Greasy, soft, yellow, white
Hair on head	Brown, scanty, coarse, curved, wavy, wrinkled	Pinkish, yellow, moderate, soft, baldness, premature graying	Black, plentiful, firm, wavy, curved
Head	Small size	Moderate in size	Big and steady
Eyes	Small, dry, thin, muddy brown, unsteady gaze, not pleasant looking	Thin, yellow, pink coppery, quickly become inflamed, pleasant looking	Big, white, pink, pleasant looking, thick, fixed, greasy
Body weight	Less	Moderate	Heavy
Action of body	Quick unsteady walk, quick actions and movements	Moderate, intelligent actions	Steady walk, slow and dignified
Eliminations	Less, constipated	Copious, watery	Moderate, solid
Strength	Less, tires quickly	Moderate	Strong, hard worker, can withstand strains
Body odor	No smell, less sweating	Heavy sweating, bad smell	Less sweating, pleasant smell
Voice	Feeble, broken, hidden, hoarse, unpleasant	High pitch	Pleasant, deep bass voice, good tone
Speech	Quick, very talkative	Moderate	Slow, definite
Sleep	Less sleep, wakeful at night	Moderate	Sleeps a good deal
Dreams	Moving in sky, action	Cold, flowers, sun, fire, lightning, red, frightful dreams	Ponds, lakes, flowers, swans, beautiful sights
Sex	Less sex capacity, less semen/menses, few children	Less sex capacity, few children	Great sex capacity
Life expectancy	Short	Moderate	Long-lived
Reaction to disease	Quick to get diseases, usually nervous disorders	Moderate, usually inflammations	Good resistance, usually cold and phlegm type
Reaction to drugs	Minimum doses required	Intolerance to drugs	Slow, tolerates at high dose

These three subtle mental energies are responsible for behavior patterns that may be altered and improved through practice and spiritual discipline, such as yoga and meditation.

HEALTH AND DISEASE

Health is defined in Ayurveda as the soundness of body *(Shrira)*, mind *(Manas)*, and soul *(Atma)*. Each part of this tripod of life should receive equal attention to ensure that the individual achieves sound health. Ayurvedic medicine stresses that psychic influences strongly affect the body in health as well as disease, a fact that must also be taken into account in modern therapeutics.

Modern science takes pride in its understanding of physiology but, in doing so, has emphasized fragmentation, isolation, and disunity. Instead of wholeness and interaction, this modern view accepts only physical objects as causes of disease, whereas these objects are merely the agents of disease, able to cause specific symptoms, but only in a susceptible host. Disease is the result of a disruption of the spontaneous flow of nature's intelligence within physiology. When people violate nature's law and cannot adequately rid themselves of the results of this action, then they acquire diseases.

Ayurveda conceives the body as being composed of three principal divisions: three *Doshas* (humors), seven *Dhatus* (tissues), and three *Malas* (excretions).

The three *Doshas* regulate cell functions. *Pit* gives energy and is responsible for cellular, enzymatic, and metabolic functions; *Kaph* helps in synthesizing blocks of cells; and *Vat* controls the other two. A balance of these *Doshas,* good quality tissues (the seven *Dhatus*), and a certain character of excretions are essential for maintaining health.

As explained earlier, an individual is born with a particular *Dosha* predominating in his or her constitution *(Prakriti).* This predominant *Dosha,* quite apart from genetic, age, environment, and dietary factors, may make an individual susceptible to a certain disease. For example, *Pit Prakriti* individuals are more prone to develop a disease syndrome with symptoms similar to a peptic ulcer. This is due to hyperactivity of the *Pit Dosha,* which regulates enzymatic activity. Hyperpepsinogenemic individuals are more susceptible to duodenal ulcer formation.[2]

Ayurveda teaches that the origin of most diseases is found either in an exogenous or endogenous *Dosha* imbalance, or in an inherent or acquired weakness of the tissues. Therefore, a successful treatment or prevention of disease consists of normalizing cellular functions through correcting any *Dosha* imbalance or improving inherent tissue vitality. For example, in the treatment of cancer, the use of agents cytotoxic to the cancer cells is important. However, equally important is potentiation of the immune system and stimulation of the body's own healing mechanisms.

MODES OF THERAPY

Once a diagnosis is made, Ayurveda offers various modes of therapy. The treatment is chosen according to patient constitution, as well as disease process. Modalities include dietary alterations, botanical medicines, minerals, animal products, exercise, yoga, meditation, counseling, and surgery.

Diet

Ayurveda places great emphasis on diet, for both its direct effect on the individual's physiologic state and its influence on the action of medicines. Proper assimilation of dietary constituents is essential for the maintenance of good health. Improper assimilation results in the formation of intermediary products of digestion that have toxic properties and are therefore treated as foreign by the body. Such toxic products are called *Ama* (this leads to the concepts of immune and autoimmune disorders).

Arthritic diseases such as rheumatoid arthritis are attributed to an accumulation of *Ama.* Could these toxic intermediates—macromolecules absorbed transmucosally from the intestine (in nutritionally insignificant amounts)—provoke strong immune reactions? The human gut has a complex system to control the continuous onslaught of antigenic substances derived from food, microorganisms, and toxins.[3] It has been suggested that absorption of such compounds could underlie the pathogenesis of disease in the gut, as well as in distant sites such as the liver and spleen.[4]

Ayurveda stresses prevention of the formation and accumulation of *Ama* through appropriate diet and the use of therapies to improve digestion. It also considers various dietary factors that trigger or eliminate certain diseases.[5] That is why Ayurveda places emphasis on diet according to the patient's psychosomatic constitution *(Prakriti),* time of day *(Dincharya),* and season *(Ritucharya).* For example, a person with the *Pit* psychosomatic constitution should not eat foods that are hot, pungent, or spicy at noon in the summer, since this tends to increase diseases of inflammation.

Ayurveda prescribes specific diets for several psychiatric disorders. Recent research supports this approach. Brain levels of the neurotransmitters 5-hydroxytryptamine, catecholamine, and acetylcholine have been found to be influenced by dietary constituents. Consequently, it has been suggested that normal brain functions and mental disease can be altered by diet.[6] Recent exciting developments include the successful treatment of mental depression with neurotransmitter precursors.[7,8]

Ayurveda also prescribes certain diets *(Pathya)* during drug therapies, since dietary constituents are believed to influence drug action.

Individualization of Medicinal Therapy

Medicinal therapy is highly individualized in Ayurveda.[9] The choice and dose of medicine are influenced not only by disease but by the individual's constitution and the environmental conditions likely to affect that individual's *Doshas.*

For example, *Piper rotudum* (black pepper) and *Zingiber officinale* (ginger), which increase *Pit* (increasing stomach acid and pepsin secretion), are used cautiously in individuals with a *Pit* constitution. Another example is in the treatment of the patient with hypertension. Ayurveda prescribes *Terminalia chebula* for the treatment of hypertensive patients who have *Vat Prakriti,* whereas for the patient with *Pit Prakriti,* one uses *Terminalia arjuna.*

In the *Vimanastrana,* Charak presented an interesting discussion of host- and drug-related factors that help in the determination of the drug and dosage (Box 32-3).

Ayurveda also emphasizes proper timing for the administration of medicines. Considering that chronopharmacology (the study of the timing of drug administration in relation to physiologic function) has only recently been developed as a branch of modern therapeutics, it seems remarkable that such astute observations about the timing of medicaments were made so many centuries ago.

Pharmacy in Ayurveda

In Ayurveda, pharmacy is highly developed. Almost 70 books contain more than 8000 recipes for the preparation of different medicines, most of which are derived from minerals and plants.

BOX 32-3 **Host- and Drug-Related Factors**

Drug Factors

Prakriti	Constitution of the drug
Guna	Properties
Prabhava	Activity (potency)
Desh	Place
Ritu	Season
Grahan	Storage
Nihit	Transport
Sanskar	Refinement
Matra	Dose
Sanyog	Combination
Adhishthan	Ability to reach site of action

Host Factors

Prakriti	Constitution of host
Vayam	Age
Vikriti	Pathologic condition
Sar	System strength
Satamya	Tolerability
Satva	Psychological state
Ahar Shakti	Digestive capacity
Vyayam Shakti	Exercise tolerance
Balam	Strength of host

Many formulations including simple distillates *(Arka),* decoctions *(Kwatha),* tinctures *(Avleha),* powders *(Churna),* pills (*Vati, Goti,* and *Modak*), fermented products *(Asva),* and medicated oils *(Taila and Ghrita)* are available. The oil preparations are particularly useful since they help to target the sites of actions.

Detailed descriptions of the methods are recommended to ensure a medicine is suitable for human use.[10] One pharmaceutic technique, *Samskara* (refinement), is known as *Shudhi* (purification), a process that eliminates the toxicity of some minerals and plants. Another practice is the administration of drugs in combination *(Samyoga)* to reduce toxicity and increase efficacy.

RESEARCH

Considerable modern research has proven the efficacy of Ayurvedic herbal preparations, and research has now moved to elucidating their mechanisms and sites of action.[11] Recent studies demonstrated probable genomic bases for metabolic differences as predicted by *Prakriti*. This genetic variant may provide newer approaches to pharmacogenomics. Extensive studies on *Prakriti* subtypes and genome mapping, especially of other important drug metabolizing enzymes polymorphisms like CYP2C19, CYP2D6, CYP2C9, CYP3A4, TPMT, etc., would be useful to understand a possible *Prakriti* pharmacogenomics relationship to its correlating genotype, *Prakriti,* and drug metabolism.[12]

Curcumin, the active principle of *Curcuma longa,* has been found to exert a powerful anti-inflammatory effect by blocking many inflammatory pathways, reversing insulin resistance, and reversing cancer by repairing defective genes.[13] Further, it has been shown to selectively inhibit platelet prostaglandin production, while sparing vascular endothelial prostaglandin synthesis.

Many plant preparations have been used to strengthen general host resistance. *Rasayna, Jeevaniya,* and *Balya* increase tissue resistance to disease, a concept similar to "prohost therapy" as put forward by Hadden.[14] Prohost therapy claims to augment cellular responses and, consequently, ameliorate disease states.[15]

A very recent paper published in *Phytotherapy Research* in May 2011 found that aqueous extract of *Withania somnifera* root had an ability to inhibit the formation of mature amyloid-β fibrils in vitro. Amyloid plaques in the brain cause Alzheimer's disease. This is an exciting discovery and may help many people from getting Alzheimer's disease.[16] Perhaps most exciting, however, is the current research demonstrating efficacy of Ayurvedic herbal preparations in conditions for which modern medicine has limited or no success. For example, animal studies showed that *Withania somnifera (Ashwagandha)* can reverse the immunosuppression of cyclophosphamide, azathioprine, and prednisolone, and a 50% alcoholic extract of *Phyllanthus emblica* protects the liver from paracetamol.[17,18] Recent human studies found that patients with acne vulgaris demonstrated substantial improvement, with no significant side effects, after using *Sunder Vati* compared with placebo. Interestingly, the study found three other Ayurvedic formulas ineffective. Patients with osteoarthritis experienced substantial, highly significant improvement in pain and disability with no significant side effects (however, the radiologic findings did not improve).[19]

AYURVEDIC AND MODERN MEDICINE

In evaluating Ayurvedic medicine by modern standards, one encounters a number of difficulties. First, there is in nature a wide variation in the quantity of pharmacologically active substances in plants. In addition, many findings are more subjective than objective. The modern scientist has difficulty recognizing subjective experiences because no reliable methodology has been developed to measure and reproduce such experiences. Yet totally objective experience, which completely disregards the subjective, may be wrong and even dangerous.

There is no such thing as complete objectivity. What people claim as such is merely agreement among many minds. Subjective experience is limited. Senses vary in ability, and reality for one is unreality for another. When using the tools of quantitative, technical science to describe biological and living systems phenomena, one soon encounters limits. Artificial distinctions must be imposed to reduce variables and interpret nonlinear events intelligibly.

Science has often confused the map for the actual reality. Take the example of color vision in bees. The eye of a bee is more sensitive to blue, violet, and ultraviolet light, whereas receptors in the human eye more readily detect red, green, and blue wavelengths. Thus, bees are nearly blind to red light, and humans are quite blind to ultraviolet light. These differing characteristics result in members of each species forming a completely different perception of the same object. Color, rather than being a part of the "reality" of a perceived object, is an expression of sensory apparatus, determined by each species' or individual's unique pattern of interneural connections. Even more interesting is the fact that, within the same species, perception may vary considerably.

Ayurvedic philosophy may strike the contemporary reader as unnecessarily complex for the conceptual territory it addresses. However, it is actually quite succinct and relevant to modern life. Its precepts have influenced many systems of healing, including naturopathic medicine, through several paths of its root traditions. It emerged alongside systems known to early Persians and Greeks, as well as the Chinese. Modern medicine is itself a distillation of these same rich traditions. When one compares Ayurvedic concepts with those of preindustrial Europe, much similarity becomes apparent.

SUMMARY

Only some glimpses of Ayurveda are presented here. This ancient system of medicine, developed over centuries, has a consistent and logical framework and gives detailed instructions for the preservation of health and the treatment of disease. Ayurveda faced a setback when modern medicine subjected all knowledge to experimental and statistical verification, which, although useful, is limited by the tools available and the perceptions underlying the questions asked. Now that considerable knowledge of cellular physiology has accumulated and more sensitive modern biomedical research tools exist, we may be able to evaluate the concepts of Ayurveda more effectively.

INTRODUCTION

The term herb refers to a plant used for medicinal purposes. Are herbs effective medicinal agents or is their use merely a reflection of folklore, outdated theories, and myth? To the uninformed, herbs are generally thought of as ineffective medicines used before the advent of more effective synthetic drugs. To others, herbs are simply sources of compounds to isolate and then market as drugs. However, to some, herbs and crude plant extracts are effective medicines to be respected and appreciated.

For many people of the world, herbal medicines are the only therapeutic agents available. In the late 1990s, the World Health Organization estimated that about 80% of the world's population relies on herbs for primary health care needs.[1] This widespread use of herbal medicines is not restricted to developing countries, since it has been estimated that 70% of all medical doctors in France and Germany regularly prescribe herbal preparations.

Although herbal medicine has existed since the dawn of time, knowledge of how plants actually affect human physiology remains largely unexplored. Many individuals formulate their view of herbal medicine based on opinion, philosophy, and ideology. This chapter seeks to facilitate an informed view of herbal medicine. The past and future of herbal medicines are discussed. We believe that the continued evolution of the tradition of herbal medicine can only be accomplished within the context of continued scientific investigation.

Throughout the world, but especially in Europe, the United States, Canada, Australia, and Japan, a tremendous renaissance in the use and appreciation of herbal medicine occurred in the latter part of the twentieth century. For example, in the United States, the sale of herbal products skyrocketed from $200 million in 1988 to more than $3.5 billion in 1997 before leveling off in the $4 billion a year range (Table 33-1). Within the European Community annual sales exceeded $7 billion in 1997.[2]

The rebirth of herbal medicine, especially in developed countries, is largely based on a renewed interest by the public and scientific researchers. During the past 20 to 30 years, there has been a huge increase of scientific information concerning plants, crude plant extracts, and various substances from plants as medicinal agents. For example, a PubMed search of the term "herbal medicine" yielded over 1300 hits in 2010. However, the number of studies of botanical medicines is much higher. For example, there were 130 studies published on *Ginkgo biloba* alone in 2010.

THE ROLE OF HERBS IN MODERN PHARMACY

Plants still play a major role in modern pharmacy. For the past 50 years, about 25% of all prescription drugs in the United States and other developed countries have contained active constituents obtained from plants. Digoxin, codeine, colchicine, morphine, vincristine, and yohimbine are some popular examples. Many over-the-counter (OTC) preparations are also composed of plant compounds. Pharmacognosy, the study of natural drugs and their constituents, plays a major role in current drug development. Unfortunately, the standard path of the approval of a drug is a process that typically takes 10 to 18 years at a total cost of roughly $250 million (Table 33-2).

Because a plant cannot be patented, plants are screened for biological activity and then the so-called "active" constituents (compounds) are isolated and typically

TABLE 33-1 **Total Estimated Herb Sales in the United States 1994-2005**

YEAR	$ TOTAL SALES (MILLIONS)	% INCREASE (-DECREASE)
1994	2020	
1995	2470	22.3
1996	2990	21.1
1997	3557	19.0
1998	4002	12.5
1999	4110	2.7
2000	4260	3.7
2001	4397	3.2
2002	4276	−2.8
2003	4178	−2.3
2004	4320	3.4
2005	4410	2.1

TABLE 33-2 **Classic Examples of Drugs From Plants With a Correlation to Its Traditional Use**

DRUG	CLINICAL USE	BOTANICAL SOURCE
Atropine	Anticholinergic	*Atropa belladonna*
Caffeine	Central nervous system stimulant	*Cola nitida*
Camphor	Rubefacient	*Cinnamomum camphora*
Cocaine	Local anesthetic	*Erythroxylon coca*
Codeine	Analgesic/antitussive	*Papaver somniferum*
Colchicine	Antigout	*Colchicum autumnale*
Digitoxin	Cardiotonic	*Digitalis purpurea*
Digoxin	Cardiotonic	*Digitalis lanata*
Emetine	Amebicide/emetic	*Cephaelis ipecacuanha*
Ephedrine	Sympathomimetic	*Ephedra sinica*
Gossypol	Male contraceptive	*Gossypium* spp.
Hyoscyamine	Anticholinergic	*Hyoscyamus niger*
Kawain	Tranquilizer	*Piper methysticum*
Methoxsalen	Psoriasis/vitiligo	*Ammi majus*
Morphine	Analgesic	*Papaver somniferum*
Noscapine	Antitussive	*Papaver somniferum*
Physostigmine	Cholinesterase inhibitor	*Physostigma venenosum*
Pilocarpine	Parasympathomimetic	*Pilocarpus jaborandi*
Podophyllotoxin	Topical wart remedy	*Podophyllum peltatum*
Quabain	Cardiotonic	*Strophanthus gratus*
Quinine	Antimalarial	*Cinchona ledgeriana*
Reserpine	Antihypertensive	*Rauwolfia serpentine*
Scopolamine	Sedative	*Datura metel*
Sennosides	Laxative	*Cassia* spp.
Theophylline	Bronchodilator	*Camellia sinensis*
Tubocurarine	Muscle relaxant	*Chondrodendron tomentosum*
Yohimbine	Male erectile dysfunction	*Pausinystalia yohimbe*

Data from De Smet PA. Drugs 1997;54:801-840.

chemically modified to produce unique substances. If the compound is powerful enough, the drug company begins the process to procure Food and Drug Administration (FDA) approval. Of 520 new drugs approved by the FDA or comparable entities in developed countries, 30 came directly from natural product sources and another 173 were either semisynthetic from a natural source or modeled after a naturally occurring compound.[1]

Because of the expense and lack of patent protection, few clinical evaluations were done before 1980 on whole plants or crude plant extracts as medicinal agents per se. A key factor in contributing to more research into herbal medicines after this time was the development in Europe of regulatory policies and practices that made it economically feasible for companies to do research. For example, in Germany, regulations allow herbal products to be marketed with drug claims if they are proven to be safe and effective.[3] Whether the herbal product is available by prescription or OTC is based on its application and safety of use. Herbal products sold in pharmacies are reimbursed by insurance if they are prescribed by a physician.

The proof required by a manufacturer in Germany to illustrate safety and effectiveness for an herbal product is less (and more appropriate) than the proof required by the FDA for drugs in the United States. In Germany, a special commission (Commission E) developed a series of 400 monographs on herbal products similar to the OTC monographs in the United States. A herbal product is viewed as safe and effective if a manufacturer meets the quality requirements of the monograph or produces additional evidence of safety and effectiveness that can include data from existing literature, anecdotal information from practicing physicians, and limited clinical studies. In contrast, in the United States, extracts that are identical to those approved in Germany as drugs are available as "dietary supplements," yet manufacturers are prohibited from making any therapeutic claims for their products. No medicinal claims are allowed for most herbal products in the United States because the FDA requires the same standard of absolute proof as required for new synthetic drugs. Thus far, the FDA has rejected the idea of establishing an independent "expert advisory panel" for the development of monographs similar to Germany's Commission E monographs, as well as other ideas to create a suitable framework for the marketing of herbal products in the United States.

The monograph system in Germany allowed companies to market their products according to the guidelines of Commission E. With the ability to make appropriate claims, many companies achieved success with their products and were enabled to fund the necessary research to gain greater acceptance within mainstream, conventional medicine. The use of St. John's wort extract in the treatment of depression is a perfect case in point to illustrate how Commission E monographs led to significant documentation of the efficacy of plants with a long history of folk use for depression.

When the Commission E monograph for St. John's wort came out in 1984, it identified the constituent hypericin as the active constituent and permitted the medicinal use of the herb (in average doses of 2 to 4 g of herb, or 0.2 to 1 mg total hypericin) for depression, anxiety, or nervous excitement.

Originally, it was thought that hypericin acted as an inhibitor of the enzyme monoamine oxidase, thereby resulting in the increase of central nervous system monoamines such as serotonin and dopamine. However, it was later shown that St. John's wort does not inhibit monoamine oxidase in vivo.[4] The antidepressant activities appear to be related more to serotonin reuptake inhibition as occurs with the drugs Prozac, Paxil, and Zoloft; modulation of neuroendocrine function; downregulation of β-adrenergic receptors; and upregulation of serotonin receptors in the brain areas

that are implicated in depression.[4,5] In addition, it appears that although hypericin is an important marker, other compounds such as flavonoids are also thought to play a major role in the pharmacology of St. John's wort. The key point here is that the further understanding and documentation of clinical effectiveness of St. John's wort extract was largely the direct result of a commercial incentive created by the existence of Commission E.[6]

Science Has Fueled the "Herbal Renaissance"

Improvements in analytic techniques and modern pharmacology have given researchers the tools and understanding necessary to evaluate herbal medicines properly. Improvements in plant cultivation techniques and the quality of herbal extracts (quality control and standardization) have also led to the development of some effective plant medicines. These advances have created a renaissance in the appreciation and use of herbal medicine. It seems that science and medicine have finally advanced to a level where nature can be appreciated rather than discounted. The scientific investigation of plant medicines is replacing some of the mystery and romance of herbalism with a greater understanding of the ways in which herbs work. Thirty years ago it was impossible to determine exactly how herbs promoted their healing effects because analytic science had not advanced to a sufficient level of sophistication. This point is well illustrated by the fact that the main mechanism of action responsible for aspirin's anti-inflammatory effect was not understood until the early 1970s, and its mechanism of action for pain relief has yet to be fully understood.

Because the mechanism of therapeutic action of a particular herb could not be fully elicited, many effective plant medicines were erroneously labeled as possessing no pharmacologic activity. Now, researchers equipped with greater understanding and more sophisticated technology are rediscovering the wonder of plants as medicinal agents. Much of the increased understanding is, interestingly, a result of synthetic drug research.

For example, one of the modern classes of drugs is calcium channel blockers. These agents block the entry of calcium into smooth muscle cells, thereby inhibiting contraction and promoting muscular relaxation. Calcium channel blocking drugs are currently being used in the treatment of high blood pressure, angina, asthma, and other conditions associated with smooth muscle contraction. They represent a highly evolved stage of modern drug pharmacy. After calcium channel drugs became better understood, it was discovered that many herbs contain components that possess calcium channel blocking activity. In most cases, the historical use of these herbs corresponded to their calcium channel blocking activity.

In addition to possessing currently understood pharmacologic activity, many herbs possess pharmacologic actions that are not consistent with modern pharmacologic understanding. For example, often an herb appears to affect homeostatic control mechanisms to aid normalization of many bodily processes. When there is a hyperstate, the herb has a lowering effect, and when there is a hypostate, it has a heightening effect. This action is totally baffling to orthodox pharmacologists, but not to experienced herbalists who have used terms such as alterative, amphoteric, adaptogen, or tonic to describe this effect.

The Advantages of Herbal Medicines

In general, herbal preparations are thought to have three major advantages: lower cost, fewer side effects, and medicinal effects that tend to normalize physiologic function. When used most effectively, the mechanism of action of an herb often corrects the underlying cause of a disorder. In contrast, a synthetic drug is often designed to alleviate the symptom or effect without addressing the underlying cause. Interestingly, research has often shown for many plants that the whole plant or crude extract is much more effective than isolated constituents. In many instances, multiple components produce multiple pharmacologic actions.

Herbal medicine will certainly play a major role in future medicine. As modern medicine gains more knowledge and understanding about health and disease, it is adopting therapies that are more natural and less toxic. Lifestyle modification, stress reduction, exercise, meditation, dietary changes, and many other traditional naturopathic therapies are becoming much more popular in standard medical circles. This illustrates the paradigm shift that is occurring in medicine.

With the continuing advancement in science and technology, there has been a great improvement in the quality of herbal medicines available and in the understanding of their optimal clinical use. Improvements in cultivation techniques coupled with improvements in quality control and standardization of potency will continue to increase the effectiveness of herbal medicines.

THE STUDY OF HERBAL MEDICINE

The study of herbal medicine spans the breadth of pharmacology, the study of the history, source, physical and chemical properties, mechanisms of action, absorption, distribution, biotransformation, excretion, and therapeutic uses of "drugs." In many respects, the pharmacologic investigation of herbal medicine is just beginning. This textbook is replete with examples of herbs whose historical use is being justified by new investigations into its pharmacology.

The History of Herbal Medicine

The history of the use of plants as medicines is full of interesting stories and fascinating facts. The evolution that occurred in herbal medicine over the centuries is only beginning to be recognized as more natural medicines gain acceptance. Interestingly, this acceptance is largely a result of increased scientific investigation.

A trend exists toward using natural substances, including compounds found in the human body, such as interferon, interleukin, insulin, and human growth hormone, as well as foods, food components, herbs, and herbal compounds. More and more researchers are discovering the tremendous healing properties of these natural compounds and their advantages over synthetic medicines and surgery in the treatment of many health conditions. Through these scientific investigations, a trend toward natural medicine is emerging. To better appreciate this evolutionary trend, this section presents some of the historical aspects of herbal medicine. Much of the following is derived from Barbara Griggs' *Green Pharmacy: A History of Herbal Medicine*.[7]

In the Beginning

Plants have been used as medicines since the dawn of animal life. The initial use of plants as medicines by humans is thought to have been a result of "instinctive" dowsing. Animals in the wild still provide evidence that this phenomena occurs. Animals, with a few notable exceptions, eat plants that heal them and avoid plants that do them harm. Presumably humans also possessed this instinct at one time.

As civilizations developed, medicine men and women were responsible for transmitting the information on herbs to their successors. Before the advent of written language, this information was handed down by verbal and experiential means.

Besides instinctive dowsing, it was commonly believed that plants had been signed by the "creator" with some visible or other clue that would indicate its therapeutic use. This concept is commonly referred to as "the doctrine of signatures." Common examples of this doctrine are the following:

- *Panax ginseng* (ginseng): its roots bear a strong resemblance to a human figure, and its general use is as a tonic.
- *Caulophyllum thalictroides* (blue cohosh): its branches are arranged like limbs in spasm, indicating its usefulness in the treatment of muscular spasm.
- *Sanguinaria canadensis* (bloodroot): its roots and sap are a beautiful blood color, corresponding to its traditional use as a "blood purifier."
- *Lobelia inflata* (lobelia): its flowers are shaped like a stomach, corresponding to its emetic qualities.
- *Hydrastis canadensis* (goldenseal): its yellow-green root signifies its use in jaundice as well as infectious processes.

All of these uses have been confirmed by recent research.

Materia Medicas

With the development of written language, materia medicas (books containing prescribing information on herbs) became the vehicle of passing information about the medicinal use of herbs to future herbalists. Materia medicas were recorded in ancient China, Babylon, Egypt, India, Greece, and other parts of the world. From these materia medicas, it is quite obvious that herbal medicines were highly respected therapies in ancient times.

Galen's Influence

No system, rules, or classification of Western herbal materia medicas existed until the first century AD, when Galen, the Greek physician who founded experimental physiology, established his system of rules and classification. Galen's classification was based on Hippocratic medicine (i.e., balance of the four humors: blood, yellow and black bile, and phlegm) and a profound belief in a beneficent nature. Although his system is considered seriously flawed in the light of modern medical knowledge, Galen is historically considered to be the founder of scientific herbalism.

Galen evaluated and classified each plant according to its relation to Hippocratic medical theory. Although based initially in Hippocratic principles, Galen constructed his own elaborate, and rigid, system of medicine. Galen's work also signified the beginning of a clear division between the professional physician and the traditional healer. As only the well educated could understand Galen's system, and even with the best schooling it remained a mystery to many, all challenges to the professional physician were effectively squelched by dogma.

Galen's system dominated European medical thinking for 1500 years. Perhaps if the Roman Empire had continued to flourish, others would have surfaced to develop alternative theories. Instead, Galenical medicine reigned unchallenged throughout the Middle Ages. By the nineteenth century, the "professional" physician, confident in his supposedly superior knowledge, took Galenical philosophy to an extreme probably never imagined by Galen, by the adoption of bloodletting, purging, and administering exotic medicines. This was in direct contrast to the traditional healer's patient use of traditional herbs and tremendous faith in the healing power of nature.

The Black Plague and Syphilis

Although Galenical medicine dominated the Middle Ages, herbal medicine was still deeply entrenched in European culture. The Black Plague of 1348 may have been the beginning of change in medical thought, since conventional medicine was totally useless. As nearly one third of Europeans died during this plague, the public began to lose faith in Galenical medicine. Nearly 150 years later another blow was dealt to Galenical medicine, when syphilis became the major medical problem. Unlike the Black Death, patients with syphilis tended to survive longer, giving physicians more time to experiment with treatments. At this time, perhaps the greatest hoax in the history of medicine began. Mercury became the standard medical treatment for syphilis despite the fact that even Galen thought mercury too poisonous to use.

Syphilis did, however, open the door for the use of some new herbs from the Americas. A French physician, Nicholas Monardes, published a comprehensive account of sarsaparilla and several other "new" drugs in the treatment of syphilis in 1574. Many Europeans at the time believed that syphilis had come to Europe from the West Indies with Columbus's sailors, and because there was a general belief that whatever disease was native to a country might be cured by the medicinal herbs growing in that region, it was only natural for sarsaparilla to become a popular remedy. Because the standard treatment of syphilis was the use of mercury, which often resulted in greater morbidity than did syphilis, sarsaparilla was a welcome alternative. Despite initial excitement, Monardes' sarsaparilla cure eventually lost favor, probably due to other components in the cure; specifically, patients were confined to a warm room for 30 days and for the following 40 days were required to abstain from both wine and sexual intercourse.

Although the public popularity of sarsaparilla waned, it continued to be used in the treatment of syphilis. During military operations in Portugal in 1812, a British Inspector General of Hospitals noted that the Portuguese soldiers suffering from syphilis who used sarsaparilla recovered much faster and more completely than their British counterparts who were treated with mercury.

Sarsaparilla was also used by the Chinese in the treatment of syphilis. Later clinical observations in China would demonstrate, through the use of blood tests, that sarsaparilla is effective in about 90% of cases of acute syphilis and 50% of cases of chronic syphilis.

Although sarsaparilla was clearly more beneficial than mercury in the treatment of syphilis, mercury was the standard medical treatment of choice for more than four and a half centuries. Some historians have stated that "the use of mercury in the treatment of syphilis may have been the most colossal hoax ever perpetrated" in the history of medicine. Mercury represented a new kind of medicine, one formulated and prepared in a laboratory using the new techniques of chemistry. It helped to prepare the way for future synthetic and mineral drugs at the expense of herbal medicines.

Challenges to Galenical Medicine

The 1500s also saw a strong challenge to Galenical medicine from within the traditional circles. Specifically, Paracelsus, an alchemist who believed strongly in the doctrine of signatures, was responsible for founding modern pharmaceutic medicine. Paracelsus is

probably most remembered for the development of laudanum (tincture of opium). After Paracelsus, Galenical preparations and treatments fell greatly out of favor.

In public circles, herbal medicine was regaining some respect as well. In the early 1600s, Culpepper, an English pharmacist, published his book *The English Physician*. Instead of requiring patients to purchase expensive exotic or imported drugs, Culpepper recommended the herbs his clients and readers had growing in their own backyards. Although Culpepper's herbal philosophy is based on astrologic rationalizations, it reinforced a strong English tradition of domestic herbal medicine. This came at a time when professional physicians were beginning to become contemptuous of herbal medicine.

Meanwhile, in the Americas during the 1600 and 1700s, herbs used traditionally by Native Americans were becoming quite popular, especially in the treatment of malaria and scurvy. Herbal medicine continued to gain even greater respect in the late 1700s, as exemplified by English physician Withering's classic description of digitalis. However, mercury, bleeding, and purging were still the "standard" medical treatments, epitomized by George Washington's death from complications incurred during treatment of a sore throat (i.e., he was bled to death).

The Thomsonian and Eclectic Movements

During the early 1800s, standard medicine may have been ready to reconsider traditional herbal remedies, but then came the Thomsonian movement. Samuel Thomson (1769-1843) patented a system of herbal medicine that, in 1839, claimed more than 3 million faithful followers. Although Thomson brought back to medicine the vitalistic Hippocratic idea of vis medicatrix naturae and gained widespread public support for the use of herbal medicine, the Thomsonian movement was probably detrimental to medical reform.

Thomsonians became locked in prejudice and dogma and insisted that all medical knowledge was complete and could be found in Thomson's works. These and other claims roused scorn, indignation, rage, and resentment in the average North American doctor. Frequently based on purging through the use of herbal emetics, Thomson's treatments were often as harsh as the standard treatments of the times (for further discussion, see Chapter 4).

During the 1800s, the eclectic movement attempted to bridge the gaps between standard medical thought, Thomsonianism, and traditional herbal medicines. Rather than attack the existing medical system, the eclectic movement sought to bring about reform by educating physicians about the use of herbal medicines. Several eclectic medical colleges were established and, for a while, it appeared that the eclectic movement was making headway in its attempt to reform the medical system from within.

The movement eventually failed, however. Several factors were probably responsible for this: a split in the ranks, which diluted the movement; harsh measures like mercury, calomel, and bloodletting were finally discarded by the conventional professional physician, due to a decrease in infectious disease as a result of improved sanitation and hygiene; and, perhaps most important, the failure to establish and sustain quality medical schools.

The Flexner report on medical education in 1910 spelled doom for the eclectics; by 1920, seven of the eight schools that had existed before the report closed, with the last school closing in 1938. Meanwhile, the standard medical schools, aided by the Rockefeller Foundation, flourished, promoting the growth of the modern pharmaceutic industry and the current near-monopoly of the medical profession.

The Growth of the Pharmaceutic Industry

Because a plant cannot be patented, little research was done before the latter part of the twentieth century. Instead, pharmaceutic firms and researchers screened plants for biological activity and then the so-called active constituents were isolated and chemically modified to produce unique, patentable compounds. Much to the dismay of the researchers was the discovery that in many instances the isolated constituents were less biologically active than the crude herb. Because the crude herb provided no economic reward to the American pharmaceutic firm, the crude herb or extract never reached the marketplace. In contrast, European policies on herbal medicines made it economically feasible for companies to research and develop phytopharmaceutics. The policies in the United States contributed to the tremendous growth of the pharmaceutic industry and loss of appreciation and respect for herbal medicine.

The herbal industry further compounded the problem by failing to provide quality herbal products or take advantage of technologic advances that allowed for standardization of chemical constituents. The herb that best exemplifies the failure to adopt standardization techniques is digitalis. One batch of crude digitalis might have a low level of active constituents, making the crude herb ineffective, whereas the next batch might be unusually high in active constituents, resulting in toxicity or even death, when standard amounts are used. The lack of standardization made it easier for U.S. pharmaceutic firms to rationalize their economic need to isolate, purify, and chemically modify the active constituents of digitalis so they could market these compounds as drugs. The problem with using the pure active constituent is that the safe dosage range is smaller: digitalis toxicity and death have increased dramatically as a result of purification. Toxicity was less of a factor when using the crude herb because overconsumption of potentially toxic doses resulted in vomiting or diarrhea, thus avoiding the severe heart disturbance and death that now occur with pure digitalis cardiac glycoside drugs.

Fortunately, several European and Asian pharmaceutic firms began specializing in phytopharmaceutics in the latter half of the twentieth century. These companies have played a prominent role in researching, developing, and promoting herbal medicines.

Research is demonstrating that crude extracts often have greater therapeutic benefit than the isolated "active" constituent. This has been long known in other parts of the world, but in this country, isolated plant drugs are still thought of as having the greatest therapeutic effect. This myth is gradually being eroded as our knowledge of herbal medicines increases.

If current standardization techniques had been available earlier in this century, it is possible that many current prescription drugs would be herbal extracts instead of isolated and modified active constituents or synthetic chemicals.

FINAL COMMENTS

Although the future looks extremely promising for herbal medicine, ultimately its growth and continued success will be determined by the following:

- Continued scientific investigation and clinical research
- Adoption by manufacturers of recognized standards of quality
- Governmental regulations that allow meaningful therapeutic claims

INTRODUCTION

The clinical application of botanical medicine involves the use of various herbal preparations. That being the case, it is imperative that practitioners and physicians using herbal medicines understand the differences among the various forms. Commercial herbal preparations are whole fresh and dried herbs, teas, tinctures, fluid extracts, and tablets or capsules. In addition, juices, purified compounds, and specific fractions of plants (e.g., volatile oil preparations) can also be considered herbal medicines. Each form has advantages and disadvantages and varying ways of expressing its medicinal strength. Any form may be an effective medicine as long as it can deliver an effective dosage of active compounds. The following section reviews the major extraction forms, discusses the benefits of standardized botanical extracts, and emphasizes the importance of delivering a clinically effective level of active compounds regardless of the form of the herbal preparation.

Types of Extracts

An extract is a concentrated form of an herb obtained by mixing the crude herb with an appropriate solvent (such as alcohol or water, or both). A major advance in the herb industry has been the improvement in extraction and concentration processes.

When an herbal tea bag is steeped in hot water, it is actually a type of herbal extract known as an infusion. The water is serving as a solvent in removing some of the medicinal properties from the herb. Teas are often better sources of bioavailable compounds than powdered herbs, but are relatively weak in action compared with tinctures, fluid extracts, and solid extracts. These forms are commonly used by the lay public and herbal practitioners for medicinal effects.

Tinctures are typically made using an alcohol and water mixture as the solvent. The herb is soaked in the solvent for a specified amount of time, depending on the herb. This soaking is usually from several hours to days; however, some herbs may be soaked for much longer periods of time. The solution is then pressed out, yielding the tincture.

Fluid extracts are similar to, but more concentrated than, tinctures. Although they are most often made from hydroalcoholic mixtures, other solvents may be used (e.g., vinegar, glycerin, propylene glycol). Commercial fluid extracts are usually made by distilling off some of the alcohol, typically by using methods that do not require elevated temperatures, such as vacuum distillation and counter-current filtration. However, some small manufacturers produce fluid extracts in a similar manner to tinctures via percolation at room temperature.

A solid extract is produced by further concentration of the extract by the mechanisms described earlier for fluid extracts, as well as by other techniques such as thin-layer evaporation. The solvent is completely removed, leaving a viscous extract (soft solid extract) or a dry solid extract depending on the plant, portion of the plant, solvent, and drying process (if any) used. The dry solid extract, if not already in powdered form, can be ground into coarse granules or a fine powder. A solid extract can also be diluted with alcohol and water to form a fluid extract or tincture.

Strengths of Extracts

The potencies or strengths of herbal extracts are generally expressed in two ways. If they contain known active principles, their strengths are commonly expressed in terms of the content of these active principles. Otherwise, the strength is expressed

in terms of their concentration. For example, tinctures are typically made at a 1:5 to 1:10 concentration. This means one part of the herb (in grams) is soaked in five parts solvent (in milliliters of volume), meaning there is five times the amount of solvent (alcohol/water) in a tincture as there is herbal material. Fluid extracts are typically 1:1.

A 4:1 concentration means that one part of the extract is equivalent to, or derived from, four parts of the crude herb. This is the typical concentration of a solid extract. A quantity of 1 g of a 4:1 extract is concentrated from 4 g of crude herb.

Typically, 1 g of a 4:1 solid extract is equivalent to 4 mL of a fluid extract and 20 to 40 mL of a tincture. Some solid extracts are concentrated as high as 100:1, meaning it would take nearly 100 g of crude herb, or 100 mL of a fluid extract, or 1 L of a tincture, to provide an equal amount of herbal material in 1 g of a 100:1 extract.

Determining Quality

Before the 1980s, the quality of the extract produced was often difficult to determine because many of the active principles of the herbs were unknown. However, advances in extraction processes, coupled with improved analytic methods, reduced this problem of quality control.[1,2] The concentration method of expressing the strength of an extract does not accurately measure potency because there may be great variation among manufacturing techniques and raw materials. By using a high-quality herb (i.e., rich in active compounds), it is possible to have a more potent dried herb, tincture, or fluid extract compared with the solid extract that was made from a lower quality herb. Standardization of herbal extracts for key active constituents has been suggested to be the solution to this problem.[3]

Standardized Extracts: The Best Solution

Standardized extracts (also referred to as guaranteed potency extracts) refer to an extract guaranteed to contain a "standardized" level of active compounds or key chemical marker. Stating the content of active compounds or key chemical marker rather than the concentration ratio allows for more accurate dosages to be made. However, the complex composition of an herbal medicine makes it unwise to ignore the other constituents.

The best scenario for determining the quality of an herb is the level of active components or key biological markers, along with taking into consideration the complete chemical profile. Regardless of the herb's form, it should be analyzed to ensure that it contains these components at an acceptable standardized level. More accurate dosages can then be given. This form of standardization has emerged as the preferred method, but it is not without its shortcomings. Chief among them is that assigning too much importance to individual components rather than the entire chemical profile leads to the assumption that controlling for the level of marker compounds is equivalent to controlling the entire pharmacologic effect of the herbal medicine. However, stating the content of active constituents versus drug concentration ratio does allow for more accurate dosages to be based on active constituents and provides the greatest degree of consistency and assurance of quality, especially if attention is also given to the other constituents.

Although referred to in terms of active constituents, it must be kept in mind that these are still whole extracts and not isolated constituents. For example, a *Uva ursi* extract standardized for its arbutin content, say 10%, still contains all of the synergistic factors that enhance the active ingredient's function.

Techniques Used in the Production of Herbal Products

A tremendous range of sophistication exists in processing herbs, from crude herb to highly concentrated standardized extracts. Nonetheless, there are some common stages. Some of the processes in the production of herbal products and the machines that perform these functions are discussed in the following section.[3]

Collection/Harvesting

When plants are collected from their natural habitat, they are said to be "wild-crafted." When they are grown using commercial farming techniques, they are said to be "cultivated." Collection of plants from cultivated sources ensures that the plant collected is the one that is desired. When an herb is wild-crafted, there is a greater chance of picking the wrong herb and of variation in potency. However, some herbal practitioners believe that wild-crafted herbs are inherently superior because growth in their natural habitat produces an herb with constituents and properties more consistent with traditional use. The use of analytic techniques can be employed to guarantee that the plant collected is the one desired and that its concentrations of medicinal constituents are within an acceptable range.

Herbs from all over the world are marketed in the U.S. marketplace. Herb collectors vary from uneducated natives to self-proclaimed "herbalists" to trained botanists.

The mode of harvesting varies from hand labor to sophisticated equipment. The mode is not as important as the time of year. A plant should be harvested when the part of the plant being used contains the highest possible level of active compounds. Again, this is ensured by using analytic techniques.

Drying

After harvesting, most herbs have a moisture content of 60% to 80% and cannot be stored without drying. Otherwise, important compounds could break down or microorganisms could contaminate the material, or both. As many of the desired compounds are heat labile, the majority of herbs require relatively mild conditions for drying. Commercially, most plants are dried within a temperature range of 100°F to 140°F. During drying, the plant constituents must not be damaged or suffer losses that would prevent them from conforming to accepted standards. With proper drying, the herb's moisture content is reduced to less than 14%.

Garbling

Garbling refers to separation of the portion of the plant to be used from other parts of the plant, dirt, and other extraneous matter. This step is often done during collection. Although there are machines that perform garbling, garbling is usually performed by hand.

Grinding

Grinding or mincing an herb means mechanically breaking down either leaves, roots, seeds, or other parts of a plant into small pieces ranging from larger course fragments to fine powder. Grinding is employed in the production of crude herbal products, as well as in the initial phases of extracts.

Often the material must be pre-chopped or minced before feeding it into a grinder. In the process of grinding, a number of machines can be used, but the most widely used is the hammer mill. These machines are simple in design. The hammers, arranged radially, follow the rotation of the shaft to which they are attached, breaking up the material that is fed into the machine from above. On the walls of the chamber is a grid, which determines the size of

the material that is passed through it. Other types of grinders include knife mills and teeth mills.

Extraction

The process of extraction is used in making tinctures, fluid extracts, and solid extracts. Extraction in the context of this textbook refers to separating, by physical or chemical means, the desired material from a plant with the aid of a solvent. In the U.S. health food industry, most extracts use alcohol and water mixtures as solvents to remove soluble compounds from the herb. The exceptions are liposterolic extracts, which are produced either through the use of lipophilic solvents or with the aid of hypercritical carbon dioxide (carbon dioxide gas compressed to a liquid by high pressures).

Most extracts that are produced by small manufacturers use maceration procedures. The simplest process consists of soaking the herb in the alcohol/water solution for a period of time and then filtering it. For many botanicals, this process yields a lower quantity of active constituents at a higher price because of the cost of the solvent. Because tinctures are 1:5 concentrates, 80% of the bottle is alcohol and water and only 20% is herbal material. In essence, the cost of the alcohol is a major portion of the retail price of tinctures.

Larger manufacturers use more elaborate techniques to ensure that the herb is fully extracted and the solvent is reused. For example, counter-current extraction is often used. In this process, the herb enters the column of a large percolator composed of several columns. The material to be extracted is pumped through the different columns at a specific temperature and flow speed, where it continuously mixes with solvent. The extract-rich solvent then passes into another column, while fresh solvent once again comes into contact with herbal material as it is passed into a new chamber. In this process, complete extraction of health-promoting compounds can be performed. The extract-rich solvent is then concentrated by the following techniques.

Concentration

After extraction of the herb, the resulting solutions can be concentrated into fluid extracts or solid extracts. In large manufacturing operations, techniques and machines such as thin-layer evaporators are used to ensure that the extracted plant components are not damaged. These machines work by evaporating the solvent and leaving the plant compounds. The solvent vapors pass into a condenser whereby they return to a liquid for reuse. The result is separation of the extracted materials from the solvent so that the final product is a pure extract, and the solvent can be used again and again.

Drying of Extracts

Many practitioners prefer the extract dried to a solid form because it is more chemically stable and lower in cost (alcohol is often more expensive than the herb). In addition, tinctures, fluid, and soft extracts can more easily be contaminated by bacteria and other microorganisms. Liquid forms of extracts also promote reactions that eventually break down some active constituents. A number of drying techniques are employed, including freeze-drying and spray drying (atomization). The result is a dried powdered extract that can then be put into capsules or tablets.

Excipients

The same excipients used in the manufacture of drug preparations and vitamin and mineral supplements are often used in the production of tablets and capsules containing herbs or herbal extracts. Many manufacturers provide a list of excipients contained in their products.

ANALYTIC METHODS

Improvements in analytic methods have definitely led to improvements in harvesting schedules, cultivation techniques, storage, stability and concentration of active compounds, and product purity. All of these gains have resulted in tremendous improvements in the quality of currently available herbal preparations.

Methods currently used in evaluating herbs and their extracts include the following:

- Organoleptic
- Microscopic Evaluation
- Physical/Chemical Analysis
- Chromatography
- Biological Analysis

Organoleptic

Organoleptic means the "impression of the organs." Organoleptic analysis involves the application of sight, smell, taste, touch, and occasionally even sound to identify the plant. Typically, the initial sight of the plant or extract is so specific it is easily recognized. If this is not enough, perhaps the plant or extract has a characteristic odor or taste. Organoleptic analysis represents the simplest, yet the most human, form of analysis.

Microscopic Evaluation

Microscopic evaluation is indispensable in the initial identification of herbs, as well as in identifying small fragments of crude or powdered herbs. It is also important in the detection of contaminants and adulterants (e.g., insects, animal feces, mold, fungi). Every plant possesses a characteristic tissue structure, which can be demonstrated through study of tissue arrangement, cell walls, and configuration when properly mounted in stain reagents and media.

Physical/Chemical Analysis

In crude plant evaluation, physical methods are often used to determine the solubility, specific gravity, melting point, water content, degree of fiber elasticity, and other physical characteristics. Various chemical/physical methods are also used to determine the percentage of active principles, alkaloids, flavonoids, enzymes, vitamins, essential oils, fats, carbohydrates, protein, ash, acid-insoluble ash, or crude fiber present.

Chromatography

The most sophisticated analytic processes involve more highly technologic assays to determine quality. Advanced techniques such as thin-layer chromatography, high-pressure liquid chromatography, capillary electrophoresis, and nuclear magnetic resonance are used to precisely separate, identify, and quantify molecules. The readings from these machines provide a chemical "fingerprint" as to the nature of chemicals contained in the plant or extract.[4] These techniques are invaluable in the effort to identify herbs, as well as to standardize extracts.

Biological Analysis

The plant or extract can also be evaluated by various biological methods, mostly in vitro or animal tests, to determine pharmacologic activity, potency, and toxicity.

QUALITY CONTROL IN HERBAL PRODUCTS

Quality control refers to processes involved in maintaining the quality or validity of a product. Regardless of the form of herbal preparation, some degree of quality control should exist. Without quality control, there is no assurance that the herb contained in the bottle is the same as what is stated on the outside. One of the key solutions to the quality control problem that exists in the United States is for manufacturers and suppliers of herbal products to adhere to quality control standards and good manufacturing practices. With improvements in the identification of plants by laboratory analysis, consumers should at least be guaranteed that the right plant is being used. Consumers, health food stores, pharmacists, herbalists, and physicians who use or sell herbal products should ask for information from the suppliers of herbal products on their quality control process. What do they do to guarantee the validity of their product? As more consumers, retailers, and professionals begin demanding quality control from the suppliers, manufacturers will use more quality control processes.

Currently, only a few manufacturers adhere to complete quality control and good manufacturing practices. Companies supplying standardized extracts currently offer the greatest degree of quality control; hence, these products typically offer the highest quality. The production of standardized extracts seeking registration in Europe may serve as a model for quality control processes for all forms of herbal preparations (Box 34-1). In general, it is believed that if the active components of a particular herb are known, whatever the form of the herb product, the herb should be analyzed to ensure that it contains these components at a medicinally appropriate level. More accurate dosages can then be given. Products should also be subjected to bacteriologic counts and be free of contaminants.

The Issue of "Phytoequivalence"

It is often difficult to translate the effectiveness of a particular form of an herbal product to another form. For example, how many milk thistle *(Silybum marianum)* seeds are required to produce the same effects as those demonstrated in clinical studies conducted on milk thistle extracts standardized to contain 70% silymarin? Or does an extract of St. John's wort that is standardized to contain 0.3% hypericin and 3% to 5% hyperforin, but whose remaining chemical profile is substantially different from the clinically proven St. John's wort, produce the same benefits? The real answers to these questions require investigations into phytoequivalence and pharmacokinetics.

The concept of phytoequivalence dictates that if a particular extract demonstrates certain clinical results, a second extract can only be considered as being equivalent if it possesses the same chemical profile as the first extract. This definition of phytoequivalence requires that not just the level of marker compounds or key active constituents, or both, be the same, but that the extracts be identical in the complete spectrum and quantity of all constituents. However, assuring identical chemical equivalence may not assure true therapeutic equivalence if pharmacokinetic factors are not taken into consideration regarding how the herbal medicine is delivered. True phytoequivalence may not be related to having identical extracts but rather to being able to produce the same pharmacokinetic pattern.

BOX 34-1 List of Quality Control Steps Necessary for the Registration of Plant-Based Drug Formulation

1. Selection of suitable plant material
2. Botanical investigation using organoleptic and microscopic techniques
3. Chemical analysis using appropriate laboratory equipment
4. Screening for biological activity
5. Analysis of active fractions of crude extracts
6. Isolation of active principles
7. Determination of chemical structure of active principles
8. Comparison with compounds of similar structure
9. Analytic method developed for formulation
10. Detailed pharmacologic evaluation
11. Studies performed to determine activity and toxicity of formulation
12. Studies on absorption, distribution, and elimination of herbal compounds
13. Clinical trials performed to determine activity in humans

Standardized Extracts Versus Tinctures

Several misconceptions regarding standardized extracts need to be addressed. One is that standardizing an extract results in the loss of important compounds. This is simply not true for the vast majority of standardized extracts. Chemical analysis of standardized extracts and tinctures, whether it be thin-layer chromatography or high-pressure liquid chromatography, has clearly demonstrated that standardized extracts are not only higher in active compounds but also have a broader range of chemical constituents due to more effective extraction.

Another common misconception is that they are more expensive than alcohol-based tinctures and fluid extracts. Calculations based on the cost of delivery of an effective dosage show that the standardized extract is significantly more cost effective. This is because, as noted earlier, there is less of the herb in tinctures and fluid extracts, resulting in consumers paying extra for alcohol, the bottle, and the cost of shipping.

FINAL COMMENTS

The effectiveness of any herb or herbal product from a pharmacologic perspective is dependent on providing an effective dosage of active compounds. Regardless of the form of the herbal preparation, clinical effectiveness requires delivery of an active dosage. At this time, standardization or accurate analysis of the content of active constituents or key biological markers is the only real assurance of the delivery of an effective dosage.

This view should not be controversial. Unfortunately, controversy arises from the fact that, from a pharmacologic perspective, it is unlikely that the dosage schedules historically recommended for most herbal tinctures are sufficient to produce significant pharmacologic effects. Although tinctures of such potentially toxic herbs as Gelsemium, aconite, belladonna, and digitalis often produce a pharmacologic effect when given at low dosages, for most common medicinal herbs, it is difficult to produce an adequate and cost-effective response when the herb is administered in tincture form.

The administration of small dosages of herbs in tincture form is an offshoot of the homeopathic and eclectic use of "mother tinctures" and "specific medicines." The effectiveness of these preparations and their ability to exert pharmacologic effects have not been proved for all but a few botanicals.

The systems of herbal medicine that have been proved to a large extent are based on delivering much higher levels of herbal

compounds than those easily obtained via the use of tinctures. Specifically, we are referring to the use of highly concentrated standardized extracts from Europe and the use of herbal preparations in Traditional Chinese Medicine and Ayurveda. In Traditional Chinese Medicine, the typical daily dose of prescribed crude herbal material is approximately 20 g. This high level of dosage is in stark contrast to a much smaller average amount of the herbal material recommended in the *British Herbal Pharmacopoeia* of 2 to 4 mL of a 1:5 tincture, which provides less than 1 g of herbal material. This difference in dosage may explain the differences in popularity of herbal medicine in China, Japan, India, and Germany compared with its relative obscurity in England, as well as in the United States before the previous decade. The key point is that herbal medicine is not going to be popular if it is not effective. It can be argued that the greater the effectiveness, the greater the popularity.

The tremendous growth noted in the United States since the mid-1980s is, in our opinion, the result of the influx of high-quality standardized extracts into the marketplace. Developments in cultivation, extraction, and concentration processes led to the successful commercial development of these herbal products. Better clinical results were achieved with these herbal medicines because they were able to deliver an effective dose of active constituents.

Although the future looks extremely promising for herbal medicine, ultimately its growth and continued success will be determined by the following:

- Continued scientific investigation and clinical research
- Adoption by manufacturers of recognized standards of quality
- Governmental regulations that allow meaningful therapeutic claims

ENVIRONMENTAL TOXIC LOAD

The twentieth century, with its promise of "Better Living Through Chemistry," brought us a host of chemical toxicant-related illnesses (referred to here as "environmental illnesses"). We are experiencing the new medical diagnoses of sick (closed) building syndrome[1,2] and multiple chemical sensitivity,[3-5] both of which are known to be related to overexposure to environmental contaminants. The rates of asthma, allergy, autism, attention deficit hyperactivity disorder, and childhood brain tumors, obesity, and diabetes are all skyrocketing. All of these have been linked to the growing environmental burden that is carried by all persons. The primary physiologic action of the major pesticide classes disrupts neurologic function.[6] The primary physiologic action of solvents is neurotoxicity[7] as well. In addition to being neurotoxic, these compounds are profoundly immunotoxic[8-10]and are often toxic to the endocrine system as well.[11-13] The adverse health effects are not limited to those systems as these compounds can also cause a variety of dermatologic, gastrointestinal, genitourinary, respiratory, musculoskeletal, and cardiologic[13-15] problems. A great many of the adverse effects of these environmental toxins appear to be secondary to their mitochondrial damaging capacity.

The Toxic Burden

In an effort to identify what the full burden of environmental chemicals in the U.S. population is, the Centers for Disease Control (CDC) has been performing an ongoing assessment of the levels of environmental chemicals in the U.S. population. This ongoing study utilizes laboratory samples from persons involved in the National Health and Nutrition Examination Survey from the years 1999 to 2000, 2001 to 2002, and 2003 to 2004 (each representing about 2400 persons). In the First National Report on Human Exposure to Environmental Chemicals, 27 different compounds were measured.[16] They tested for the presence of 13 different heavy metals, cotinine, six different organophosphorus pesticide (OP) metabolites, and seven phthalates and their metabolites. Nine of the heavy metals (including lead and mercury), three of the organophosphorus metabolites, and three of the phthalate metabolites appeared fairly ubiquitously. The second report was published 2 years later and expanded its scope of measurement by an additional 89 compounds for a total of 116 chemicals for the years 1999 and 2000.[17] The second report included measurements of dioxins, furans, polycyclic aromatic hydrocarbons (PAH), herbicides, carbamate pesticides, certain organophosphate pesticides (including chlorpyrifos), phytoestrogens, and organochlorine pesticides. Of the 14 PAHs measured (all from combustion) five were found ubiquitously. In the third report (2005), pyrethroid insecticides were added to the list.[18]

In the fourth report, 75 new compounds were measured, bringing the grand total of measured xenobiotics to 212.[19] This report included blood and urinary levels of eight different forms of arsenic along with several aromatic solvents (a total of 30 different compounds) for the first time. This was also the first of the reports that gave values for mercury in adults rather than juveniles and showed that the majority of mercury in the blood is organic rather than elemental. Acrylamides, trihalomethanes (from water disinfection), bisphenol A, phthalates, triclosan, polybrominated diphenyl ethers (flame retardants), benzophenone from sunblock, perfluorocarbons from nonstick coatings, and a host of other xenobiotics were found in the majority

of persons tested in the fourth report. A review of the pertinent findings of the fourth report is available online.[20]

The Environmental Working Group (www.ewg.org) has funded and published two studies that specifically tested adults and newborns in the United States for xenobiotic burden. They originally tested 9 adults for the presence of 210 environmental toxins.[21] These nine adults had an average of 91 of the 210 toxic compounds. Because these compounds can also be passed from mother to child, the EWG did a study to examine how many toxins were passed to babies. The EWG newborn study tested for 423 toxic chemicals in the cord blood of 10 infants born in U.S. hospitals in the year 2004.[22] A total of 287 toxic compounds were found in the samples of the cord blood, with an average of 200 per child. One hundred one of these toxic compounds were found in all of the samples, with a range of total chemicals from a low of 154 compounds per child to a high of 231.

These studies, and hundreds more that have been published in the medical and scientific journals, have shown that we are all burdened with numerous toxic compounds. Examples include the fat-soluble polychlorinated biphenyls (PCBs), chlorinated pesticides (dichlorodiphenyltrichloroethane [DDT], etc.), dioxins and furans, plastics, heavy metals, OPs, aromatic hydrocarbons from tailpipes and cigarettes, flame retardants, napthalenes, and perfluorocarbons. It is no longer a question of if we are all burdened with toxic compounds, but rather if this burden is a causative factor in our health complaints and an obstacle to cure.

Sources of Environmental Toxins

In the previous section, the EWG newborn study[22] highlighted the fact that mothers unwittingly pass fat-soluble toxins to their child during gestation. After birth, the toxic exposures primarily come from the air in our homes and the food that we consume. The U.S. Environmental Protection Agency did a number of total exposure assessment methodology studies in the 1980s, which showed that indoor air contains higher levels of environmental chemicals than outdoor air (even in towns with multiple chemical plants).[23] The majority of compounds found in the indoor air were solvents that came from smoking, dry cleaned clothes, home furnishings, and home cleaning agents. Pesticide use in the home and garden are also contributing factors to the burden of pollutants in indoor air and dust.[24,25]

Food is the other route through which the majority of our xenobiotic load is delivered. The U.S. Food and Drug Administration (FDA) has an ongoing total diet survey that measures a set list of foods for a variety of environmental contaminants, including heavy metals and plasticizer compounds.[26,27] The U.S. Department of Agriculture (USDA) has also been doing an ongoing measurement of pesticide residues on the most commonly consumed fruits and vegetables.[28] The data published in this USDA report form the basis for the "dirty dozen" list of the most toxic fruits and vegetables, which are published on the web by the EWG.[29] This listing gives the consumer information on how to avoid their greatest exposures to OPs.

Plasticizers contaminate food from simple contact with plastic food wrap. The movement of plastics from the wrapping to the food increases with the length of time they are in contact with each other, the fat content of the food, and whether or not heat is involved. Microwaving foods in plastic wrap increases migration, depending upon how closely the food is in contact with the wrapping.[30] Levels of plasticizers are high in store-wrapped meat, poultry, fish, and cheese, with cheese having the highest level of plasticizers. Contrary to a current internet myth, freezing food in plastic containers does not increase plastic levels in the food. Plastic levels in unheated plastic-wrapped foods only increased in those foods after they were heated.[31] Our exposure to some plasticizers, however, comes primarily from fragrances and other personal care products.[32]

Butter has been used as a sampling agent to assess the regional and global distribution of PCBs and other persistent organic pollutants around the globe. When butter was sampled for these compounds from around the world, the highest levels of PCBs were found in butter from Europe and North America.[33] For individuals living in North America, the greatest source of PCB exposure came from butter and fish.[34] However, by far, the single greatest source of PCBs and other "halogenated" persistent toxins in food is farmed Atlantic salmon from grocery stores and restaurants. A study done by the Food Safety Authority of Ireland found that farmed salmon had an average of four times the amount of PCBs and dioxins as wild salmon.[34a] Another study revealed that these farmed salmon had PCB levels over five times higher than those found in a sampling of wild salmon.[35]

These studies were done on relatively small numbers of fish, but had consistent findings. Their findings were confirmed in a subsequent study done on over 700 salmon, totaling approximately two metric tons of farmed and wild salmon from around the globe.[36] Thirteen persistent chlorinated chemical pollutants, including the flame retardant polybrominated diphenyl ether, were found in significantly higher levels in farmed salmon than in wild salmon.

HEALTH EFFECTS OF ENVIRONMENTAL TOXINS

Numerous studies have been published on the adverse health effects of individual xenobiotics. Although the areas of impact cover all the systems in the body, this chapter focuses on the documented immunotoxic, neurotoxic, and endocrinotoxic effects of these chemicals.

Immunotoxicity

Of the three major systems affected by xenobiotic burden (immune, neurologic, and endocrine), the signs and symptoms of immunotoxicity are very often the first to occur in a patient's history. This often begins with the appearance of allergies (including adverse food reactions), after which chemical sensitivity begins. Chronic infections (due to cell-mediated immune dysfunction) and autoimmunity can also be present.[8,9,37] Rarely will a single individual manifest all of these, but clinicians are well advised to be vigilant in looking for such a constellation.

Cell-Mediated Immune Dysfunction

Unfortunately, many of the xenobiotics that have been identified inside all of us are very potent suppressors of cell-mediated immune responses. Dichlorodiphenyldichloroethylene (DDE) (the main metabolite of DDT) causes apoptosis of peripheral blood mononuclear cells, resulting in fewer macrophages roaming the body to phagocytize invading pathogens and trigger an immune response.[38,39] Persons with the highest levels of DDE in their blood also showed reduced mitogen-induced lymphocyte response to concanavalin A.[40] Individuals with this commonly found lipophilic toxin could easily have compromised cellular immune responses. Mercury, another commonly found xenobiotic, also increases apoptosis of both monocytes and lymphocytes and reduces phagocytic ability of the monocytes. It has been demonstrated that workers occupationally exposed to mercury

vapor exhibited diminished capacity to produce both tumor-necrosis factor-α and interleukin-1.[41]

The chemicals produced by combustion, PAHs, have been shown to have similar depressing effects on the immune system, including decreased T-cell dependent antibody response, decreased splenic activity, diminished T-cell effector functions, suppression of T-cell cytotoxic induction, and lower natural killer cell activity.[42] The OPs, which are not as biologically persistent as chlorinated pesticides, are also toxic to the immune system. They have been found to cause decreased percentages of CD4 and CD5 cells, increased number and percentages of CD26 cells, increased incidence of atopy and antibiotic sensitivity, and high rates of autoimmunity. This elevation in autoimmunity is reflected by high levels of antibodies to smooth muscle, parietal cells, brush border, thyroid, myelin, and elevated antinuclear antibody (ANA).[43]

Allergy and Asthma

Increased rates of asthma and allergy have been clearly linked to outdoor air pollution.[44] A day or two after ambient ozone levels spike, persons with asthma have exacerbations of their breathing problems.[45] Hikers who encounter elevated levels of ozone also experience reduced lung function. With each additional 50 ppb of ambient ozone levels, hikers experience a 2.6% decline in forced expiratory volume and a 2.2% decline in forced vital capacity.[46] When persons with asthma and allergies encounter diesel exhaust particles, their allergic problems increase.[47] Even those individuals without a history of allergies can become allergic when exposed to diesel emissions at the same time as an allergen. Herbicide and pesticide exposures,[48] as well as exposure to phthalates (plasticizers) in house dust have also been associated with increased risk for asthma.[49]

Autoimmunity

The development of autoimmunity has been linked with chemical exposure as well. The notion of chemically-induced autoimmune states is, of course, not new because many chemicals are known to induce the onset of systemic lupus erythematosus. Some chemicals, like formaldehyde and other volatile organic compounds, are thought to induce tissue-specific autoimmune reactions by acting as haptens. These low molecular weight molecules bind to various tissues in the body, making a new antigenic combination. The immune system then makes an antibody to this new combination that can attack the parent tissue with or without the chemicals being present. Chemically exposed individuals will often present with elevated antibodies to certain body tissues, including antimyelin, antiparietal, anti-brush border, and antismooth muscle.[50] A study of 298 patients with exposure to industrial chemicals revealed several immunologic abnormalities, including autoantibodies against smooth muscle (odds ratio [OR] 3.99), parietal cells (OR 9.7), and brush border cells in the small intestine (OR 14.45), the thyroid, and myelin sheathing.[51]

Autoimmune hypothyroidism is becoming a much more commonly seen problem in physicians' offices and can be secondary to exposures beyond just OPs.[52] The presence of elevated levels of antinuclear antibodies has also been associated with pesticide exposures other than organophosphates.[53]

A number of investigators have reported that mercurials are also capable of immune activation, leading to autoimmunity while simultaneously reducing the cellular immune response leading to increased infection,[54-57] which is the classic appearance of immunotoxicity.[58] In genetically susceptible mice, the presence of mercury dramatically increased their autoimmune response with increased antifibrillarin antibodies.[59]

BOX 35-1 **Neurotoxicity Presentations**

Organophosphates
- Poor cognition
- Poor attention
- Depression
- Fatigue
- Headache
- Tremors
- Paresthesia
- Slower reaction time

Chronic Low-Level Chlorinated Pesticides
- Poor cognition
- Short-term memory loss
- Balance problems
- Depression
- Fatigue

Solvents
- Poor cognition
- Short-term memory loss
- Depression
- Irritability
- Fatigue
- Headaches

Neurotoxicity

The neurologic system is also a frequent target for xenobiotic compounds. Some patients will present primarily with neurotoxicity symptoms, whereas others may exhibit immunotoxicity signs and symptoms first. The most common neurotoxicity symptoms include reduced cognitive functioning (often referred to by the patient as "brain fog" or "crooked brain"), headache, memory problems, and mood disorders. Tremors, balance problems, and anxiety can also be present (Box 35-1). Although there are indications that xenobiotics may play a role in certain neurologic illnesses, Parkinsonism is the illness that shows the most association.

The nervous system is a unique target for toxic agents in several ways:

1. The adult neuron does not divide and, therefore, replacement of lost neurons is not possible. Nerve cells killed by toxins cannot regenerate.
2. The blood–brain barrier does not block nonpolar substances or items that are actively transported.
3. Because the normal function of the nervous system requires the action of a complex integrated network, damage to even a small portion of the nervous system sometimes can result in marked effects on function.
4. Neurons are dependent on glucose and oxygen, and some cell bodies exist at borderline levels of oxygen. If high energy demands are placed on the system and delivery of oxygen is reduced, then cell death may occur.
5. Because of high lipid content (myelin), there is an accumulation and storage of lipophylic xenobiotics.
6. Neurons have high surface areas and, therefore, increased exposure to toxins.

Unfortunately a great many of the common xenobiotic toxics in our bodies are potent neurotoxins. All of the major classes of pesticides kill pests by virtue of their neurotoxic actions. Chlorinated pesticides and pyrethroids disrupt the ion flow along the axon, whereas organophosphates (which came out of nerve gas research in Germany between the first and second world wars[60]) and carbamates are potent acetylcholinesterase inhibitors (resulting in excessive acetylcholine levels in the synaptic clefts). Solvents, some of which were originally used as anesthetics, dampen the propagation and transmission of electrical impulses along the nerve axons. All of these agents produce various forms of toxic encephalopathy (acute or chronic, selective, or diffuse toxic encephalopathies). Many environmentally ill patients present to their physicians with chief complaints that fit this diagnostic category.

Pesticide Neurotoxicity

Organophosphates. The average clinician will rarely see an individual with acute organophosphate poisoning. Instead, they will see persons presenting with depression, headache, fatigue, cognitive issues, and other problems that could tend to be attributed to other issues of aging. The following OP worker studies highlight these problems.

Greenhouse workers who were exposed to OPs exhibited higher incidences of depression, headache, tremors, and paresthesias.[61] Polish female greenhouse workers exposed to OPs exhibited longer reaction time and reduced motor steadiness than unexposed workers. They also reported increased tension, depression, and fatigue more than controls reported.[62] Dutch farmers and gardeners who used OPs frequently had much higher risk of developing mild cognitive dysfunction than others.[63] Farmers repeatedly exposed to OPs from sheep dip showed much greater vulnerability to psychiatric disorders than controls (quarry workers). They also performed worse than controls on cognitive testing that assessed attention span and how fast they processed information.[64] None of the persons in any of these studies fit the definition of acute OP toxicity and none had dramatic reductions of acetylcholinesterase.

Neurologic problems from OP exposure can also persist. A study of persons previously poisoned by OPs revealed many abnormalities, including memory, abstraction, intellectual functioning, mood, and motor reflexes. They also had greater distress and complaints of disability.[65] A different study of OP workers also revealed diminished memory, learning, and vigilance, but also found diminished plantar and ankle reflexes.[66] The authors noted that the persons with these problems had similar acetylcholine levels as those who did not exhibit these differences. Abnormal deep tendon reflexes were found, along with diminished coordination and muscle strength in Ecuadorian persons exposed to OPs.[67]

Chlorinated Pesticides. Because the use of chlorinated pesticides has been banned in the United States since the 1980s, the symptomatic picture of acute poisoning with them will not be presented. Instead, we find a picture of generalized neurologic dysfunction very similar to what was just presented for OPs.

Early controlled trials of airborne exposure to low levels of DDT revealed that exposed subjects would experience neurologic symptoms, including dimming of vision, a drawing sensation at the base of the nose or behind the eyes, a sense of fullness deep inside the skull, headache, slowness of thought, inability to concentrate, and short-term memory loss.[68] Various muscle symptoms also occurred, including weakness, fatigue, dysphagia, and ataxia. Demonstrable reductions in electromyographic readings were found after nasal exposure to DDT that might account for such symptoms.[69]

A study that compared retired malaria control workers with a reference group of retired persons who did not handle DDT revealed that the exposed group had significantly poorer performance on cognitive, sensory, and motor testing. They did particularly poorly on the cognitive testing (verbal attention, visuomotor speed, and sequencing) and reported significantly more psychiatric symptoms than controls reported.[70]

Neurologic effects of chlordane exposure were studied in a group of persons who lived in an apartment complex where chlordane was used. Seven years after the application occurred, residents and former residents of the complex were assessed. Significant changes were found in the exposed persons, including reduced reaction time, balance dysfunction (shown by increased sway speed), reduction in cognitive function, perceptual motor speed, and immediate and delayed verbal recall. They also had worse scores for mood, including increased tension, depression, anger, and fatigue.[71]

Solvents. Chronic toxic encephalopathy (CTE) from solvent exposure will often gradually improve in 50% of cases with elimination of solvent exposure (Box 35-2). However, 50% will not improve from mere avoidance in the time frame of 6 to 42 months after initial assessment. It is interesting to note that in one study persons on antidepressants were nearly four times more likely to have persistent CTE than those not on the medications.[72] Although the study failed to list which antidepressants were used, many of the antidepressant medications were known to be inhibitors of the CYP system in the liver. Workers with a genetic polymorphism affecting glutathione production had a dramatically increased risk for the development of CTE.[73] It is therefore possible that the reason for such poor recovery from CTE after leaving the main source of solvent exposure is the rate at which the liver can clear these compounds from the circulation. In persons with CTE, brain atrophy was noted in over 50% of them using computed tomographic scan.[74]

Toluene, an aromatic solvent that is commonly present in glues and paints, leads to a very classic presentation of CTE. In one study with toluene-exposed printers, the following symptoms were found: fatigue 80%, impaired memory 60%, impaired concentration 40%, irritability 37%, headaches 30%, mood lability 27%, and depression 20%.

Shipyard painters were found to have significantly higher scores for neurotic behaviors than controls reported.[75] They were also found to have significantly greater problems with short-term memory, concentration, fatigue, dizziness, and insomnia. They also noted more trouble with a feeling of pressure in the chest and perspiration without work. One of the questions most frequently answered affirmatively by the group (in significantly higher levels than controls) was, "Do you often have to go back to check things that you have done, such as turned off the stove, locked the door, etc?"[76]

Female workers exposed to toluene showed significantly more problems with manual dexterity, visual scanning, and verbal memory.[77] The authors of this study noted that the workers who exhibited these changes on neurobehavioral testing showed absolutely no clinical signs of toxicity!

Heavy Metal Neurotoxicity

Lead. Lead is a well-recognized neurotoxin leading to multiple problems in children, including reduced IQ scores,[78] and attention[79] and behavioral problems. Parents of children with lead burdens report that their children have more somatic complaints and delinquent, aggressive, internalizing, and externalizing behavior. Their teachers report that the children have more problems with anxious/depressed behavior, social problems, attention problems, and delinquent, aggressive, internalizing, and

BOX 35-2 Chronic Toxic Encephalopathy (CTE): Designations of Solvent-Induced Neurotoxicity

1. Affective syndrome: neuropsychiatric symptoms, no signs of impairment, reversible.
2. Mild chronic toxic encephalopathy: neuropsychiatric symptoms, proven impairments, uncertain reversibility.
3. Severe chronic toxic encephalopathy: more severe neuropsychiatric symptoms, more pronounced impairments, usually irreversible.

Data from World Health Organization meeting on Organic Solvents, Copenhagen, Denmark, 1985.

externalizing behavior.[80] In Yugoslavian children, specific intelligence testing revealed that lead was most damaging to perceptual–motor aspects of intelligence rather than language-related aspects.[81] Lead exposure in children may also be a factor in pervasive developmental disorders, including autism.[82] A number of studies have also clearly linked lead burden in children and attention deficit hyperactivity disorder.[83-85]

When persons who were lead exposed in childhood were studied 20 years later, neurologic deficits were still found. In this group, significant adverse central and peripheral neurologic effects were present. Peripheral nerve function was altered, as were measures of coordination, reaction time, dexterity, learning, and mood.[86] As persons with lead exposure grew older, their memory capacity continued to decline, at rates faster than aging could account for.[87]

Lead workers have consistently shown neuropsychologic problems at levels significantly higher than those of controls. These problems include visuospatial, visuomotor, comprehension, and symptoms of depression, insomnia, fatigue,[88,89] and postural sway.[90,91] When bone lead burden was measured in older individuals, none of whom had industrial exposures to lead, a clear association was correlated with mental function. As the total bone lead (measured by fluoroscopy of the tibia) increased, cognitive function decreased in a group of older individuals from Baltimore.[92]

Recently, lead burden has been associated with increased risk for the development of Parkinsonism.[93]

Mercury-Induced Neurotoxicity

Mercury in both organic and inorganic forms is neurotoxic. Methylmercury accumulates in the brain and is associated with mitochondria, endoplasmic reticulum, Golgi complex, nuclear envelopes, and lysosomes. In nerve fibers, methylmercury is localized primarily in myelin sheaths, where it leads to demyelination.[94] Mercury is also known to inhibit the uptake of dopamine,[95] serotonin,[96] and norepinephrine[97] at synaptic sites. Mercury apparently has a higher binding affinity for serotonin-binding sites.

The widespread pollution of Minamata Bay, Japan, by methylmercury in the 1950s provided researchers with a clear picture of methylmercury-induced neurotoxicity. Known as Minamata Disease, the neurotoxic signs included ataxia, speech impairment, constriction of visual fields, hypoesthesia, dysarthria, hearing impairment, and sensory disturbances. These neurologic problems persisted and were found in other areas of Japan as the mercury contamination spread through fish consumption.[98] Follow-up studies in the Minamata area almost 40 years after the spill and almost 30 years since a fishing ban was enacted for the area showed the persistence of mercury neurotoxicity. Residents in fishing villages in the area in 1995 reported significantly higher prevalences than "town resident controls" in males for the following complaints: stiffness, dysesthesia, hand tremor, dizziness, loss of pain sensation, cramping, atrophy of the upper arm musculature, arthralgia, insomnia, and lumbago. Female residents of the fishing villages had significantly higher incidents of complaints of leg tremor, tinnitus, loss of touch sensation, leg muscular atrophy, and muscular weakness.[99]

In the Amazon, children exposed to methylmercury from local gold mining have also been studied for the neurotoxic effect of methylmercury. In the villages studied, more than 80% of the children had hair mercury levels above 10 mcg/g (a level above which adverse effects on brain development are likely to occur). Neuropsychological tests of motor function, attention, and visuospatial performance in these children showed decrements associated with hair mercury concentrations.[100] Patients in an internal medicine practice in San Francisco who consumed large fish regularly and had mercury blood levels above 5 mcg/L presented most commonly with fatigue, hair loss, trouble thinking, memory loss, muscle aches, and headaches.[101] One peculiar symptom in this group was a metallic taste in the mouth.

Mental health symptoms are also quite common with mercury toxicity. Evidence linking mercury exposure to psychological disorders has been accumulating for the last 60 years. The recognized psychological symptoms of mercury include irritability, excitability, temper outburst, quarreling, fearfulness, restlessness, depression and, in some cases, insomnia. In a study of individuals with amalgam filling who had them removed, the majority noted psychological improvements. The greatest improvements were found in anger outbursts, depression, irritability, and fatigue.[102] None of these manifestations were too surprising when related to the effect of mercury on reducing the serotonin effect. The association of mercury to depression has stimulated some interesting questions as to whether mercury toxicity was to blame for Sir Isaac Newton's health problems of 1692 to 1693.[103]

Endocrine Toxicity

The most common presentations of toxic damage to the endocrine system are:

1. Sleep disturbances or changes in energy level or mood.
2. Alterations in weight, appetite, and bowel function.
3. Sexual interest and function change; in females, any menstrual change.
4. Changes in temperature perception, sweating, or flushing.
5. Alteration of hair growth and skin texture.

The most common endocrine diagnoses associated with xenobiotic burden include:

1. Infertility
2. Hypothyroidism
3. Adult-onset diabetes and obesity

Infertility

Pesticides, solvents, aromatic hydrocarbons, heavy metals, and chemical dusts have been associated with both male and female infertility.[104]

Herbicides and Organophosphate Pesticides. A study of Ontario farmers showed an association of female pesticide use with fecundity,[105] and the relative risk of being infertile from pesticide exposure was 3.8. Five compounds reduced females' fecundity rates 24% to 49%: Dicamba (0.51), glyphosate (0.61), 2,4-D (0.71), organophosphates (0.75), and thiocarbamates (0.76). Glyphosate is commonly known as "Roundup" and is highly advertised in print and on TV for its safety, yet was clearly associated with infertility in this study. In a study of Spanish greenhouse sprayers exposed to OPs, higher spontaneous abortion rates were found, along with higher rates of depression and headaches.[106] Although these health problems were clearly evident, no significant decrease in erythrocyte acetylcholinesterase was found. This reproduced other studies showing apparent adverse organophosphate health effects without the expected serum finding indicating an acute OP toxicity. A study in California farming counties showed a clear association with pesticide spraying and fetal death due to congenital anomalies.[107] In this study, when an OP or carbamate pesticide was sprayed in one of eight adjacent square miles of women's residences during the third to eighth week of pregnancy, the OR of fetal death was 1.4. When the spraying occurred within one square mile of a residence, the OR increased to 2.2.

Chlorinated Pesticides and Polychlorinated Biphenyls. Chlorinated compounds were studied in a German clinic for association with reproductive difficulties.[108] Hexachlorocyclohexane (HCH) serum levels were significantly associated with miscarriage history and uterine fibroid presence. Higher HCH and PCB levels were also noted more frequently in women with antithyroid and antinuclear antibodies. PCB exposure and elevated antithyroid antibodies have also been reported elsewhere.[109] PCB serum levels were significantly associated with endometriosis and increasing DDT levels with reduced conception. Pentachlorophenol (PCP) levels were also found to be associated with increased miscarriage rates and levels of ANA.

A noncontrolled study in Canada looked for the presence of certain xenobiotics in the serum and follicular fluid from infertile females and seminal plasma from their male partners.[110] These eighteen couples all attended an in vitro fertilization program in hopes of becoming parents. They found DDE, mirex, HCH, trichlorobenzene, and three different PCBs in more than 50% of all follicular fluid samples. Four different PCBs, DDE, and endosulfan were also found in over 50% of all serum samples. DDE was the most frequently found contaminant, had the highest residue, and was negatively associated with fertilization. Of the couples tested, those who failed to achieve pregnancy with in vitro fertilization methods generally had higher toxic levels than successful couples. It is unfortunate that these authors did not get a matched control group of fertile couples to compare the toxic burden.

In the same Canadian study, women with higher DDE levels had greater trouble conceiving. This finding was also noted in the previously mentioned German study and was recently redocumented as a generational effect as well in a group of women from Oakland, California.[111] In this study, serum levels of DDT/DDE were measured from maternal samples at the time of birth. The time it took these daughters to conceive were then followed for 28 to 31 years. Differing generational effects were found for both DDT and DDE. Maternal levels of DDT were associated with reduced fecundity (32% less) in their daughters, whereas DDE levels were associated with increased fecundity (16% greater).

Solvents. Occupational solvent exposure has been associated with infertility (OR 1.76) and tubal-factor infertility (OR 1.95).[21] Reduced fecundity has also been shown in female toluene workers (fecundity rate [FR] 0.47)[112] and in laboratory workers exposed to organic solvents (FR 0.79).[113] Toluene was also associated with a reduction in luteal phase luteinizing hormone in both males and females.[114] In laboratory workers, the greatest reduction of fertility was found in association with acetone exposure (FR 0.72). Chronic benzene exposure was associated with abnormally long menstrual cycles.[115] Wives of men who worked around organic solvents also showed decreased fecundity (FR 0.36).[116] A study in Chinese female chemical plant workers revealed an increased risk (OR 2.9) for spontaneous abortions.[117] Of the myriad of petrochemicals they were exposed to, benzene (OR 2.5), gasoline (OR 1.8), and hydrogen sulfide (OR 2.3) all showed independent significant association with miscarriages. A study in pharmaceutic factory workers also showed increased spontaneous abortion risk from multiple solvent exposures.[118] The risk increased as the number of solvents used increased, with the greatest risk found in those who were exposed to four or more solvents. In pharmacy assistants, an increased risk was found for stillbirths and perinatal death for those with solvent exposure.[119] A National Institute Occupational Safety and Health study of forest service workers exposed to two different paints used to mark trees revealed a 177% and a 181% increased risk of miscarriage over workers who were not exposed to these paints.[120] Those forest workers who were exposed to herbicides had an 82% increase in their risk as well. A single case of first-trimester maternal exposure to the solvent *N*-methyl-2-pyrrolidone, resulting in fetal death in week 31 of gestation, was also reported in the literature.[121]

Hypothyroidism

PCBs have been closely studied for their possible adverse effects on thyroid hormonal status and function. Both PCBs and thyroxine are made of two connected benzene rings with attached halogens; PCBs having chlorine molecules and thyroxine with iodine. Interestingly, the common human contaminant bisphenol-A is also structurally similar, with two bromine molecules on each of the rings. PCBs have demonstrated in vitro activity in binding transthyretin, a transport protein mechanism for thyroxine.[122] This effect of blocking the transport of thyroxine via this molecule (which does not affect thyroxine-binding globulin) is also found with dioxins and furans. They also appear to adversely affect the thyroid hormone metabolizing enzymes (uridine-diphosphate-glucuronyl transferases, iodothyronine deiodinases, and sulfotransferases) found in the liver and brain.[123]

Elevated antithyroid antibodies, both antiperoxidase and antithyroglobulin, were found in workers in a PCB manufacturing plant.[109] This is reflective of the earlier noted study,[108] in which PCBs and HCH were frequently found in infertile German women with antithyroid and antinuclear antibodies. Surprisingly, no difference was found in the levels of T4 and thyroid stimulating hormone (TSH) in these 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) workers than in the control group. One of the limitations in this and other studies looking at the effect of toxins on thyroid function is the use of TSH normal ranges. Only TSH levels that are above the upper limit of normal, showing a gross hypothyroidism, would be considered an abnormal finding. Many alternative clinicians have found that TSH levels between 3 and 5, within laboratory normal ranges, typically indicate subclinical hypothyroidism. The use of the term subclinical here can be misleading, because the individuals in questions typically present with symptoms of hypothyroidism and note dramatic symptomatic improvement with proper thyroid hormone replacement. At least some of the workers in this study with elevated antithyroid antibodies would certainly be expected to eventually have elevated TSH and reduced T3 or T4 levels and would have found symptomatic improvement with replacement of these hormones.

A recent study in Sweden examined women who were exposed to PCBs from consuming at least two meals of fish from the Baltic Sea each month. Their PCB serum levels were measured along with their FT3, TT3, FT4, and TT4 levels, which revealed a significant inverse correlation between PCB levels and TT3 and an insignificant inverse correlation with TT4.[124] German children showed a significant positive correlation between PCB serum levels and elevation of TSH.[126] They also showed a significant inverse correlation between serum PCB levels and FT4, as one would expect to find with increasing TSH levels.

Chlorinated pesticides have also been associated with hypothyroidism. A study of Indian women looked for any association between DDT and dieldrin in women with elevated TSH and depleted T4. DDT was found to be higher in all of the hypothyroid women, though not significantly, but dieldrin was significantly associated with low T4 levels.[125] As mentioned previously, pesticide applicators had elevated TSH levels during the seasons in

which they sprayed most (summer to fall). These applicators used both OPs and fungicides.

Adult-Onset Diabetes

The incidence of adult-onset diabetes has risen in the last decade at rates much higher than previously recorded.[127,128] Although there is clear association with a variety of lifestyle choices to the risk of diabetes, new information is also pointing to a xenobiotic link.[129] Arsenic, naturally present in groundwater throughout the world, has been associated with the development of diabetes.[129,130] Arsenic is present in some of the following foods: shellfish, chicken, and rice, and is high in cigarette smoke. The presence of chlorinated pesticides and dioxins have also been linked to the development of diabetes.[131] In this study, the OR for developing diabetes was 2.5 for those with the lowest levels of PCB 153 in their blood and was 6.8 for those with the highest levels. The chlordanes trans-nonachlor and oxychlordane had ORs of 2.7 (each) for those with the lowest blood levels of these termiticide residues, and ORs 11.8 and 6.5, respectively, for those with the highest blood levels present. When the sum of all six bioaccumulative toxins were combined, the odds of developing diabetes went from a low of 14-fold to a high of 37.7-fold for those with the greatest fat-soluble burden. Studies examining other persistent pollutants have also revealed greater diabetes risk.[132]

DIAGNOSTIC METHODS

A comprehensive history is the cornerstone of detecting xenobiotic-induced health problems. While taking a history, special attention should be paid to both occupational and nonoccupational chemical exposures. Occupational exposures are usually the easiest to document, and should always be followed up with a request for the Material Safety Data Sheet on each chemical from the employer. Nonoccupational exposures are harder to document, but in a family practice are often found to be the main culprit. Specific questions should be asked about the history of residences: where the patient lived, how new the structure is, age of carpeting, time of remodel, type of heating, use of indoor or outdoor pesticides, attached garage, etc. Once the history of residential exposure is garnered and compared with the chronologic symptom history, the answer may become quite clear.

However, because of the ubiquitous nature of the chemicals in question, a history may not always give a clear picture of exposure. Other laboratory tests may be helpful in these cases. A standard complete blood count and general blood chemistry test is usually nonremarkable in cases of chronic low level exposures (although the author often finds leukopenia present in his population of toxic patients). In his patient population, the author rarely finds elevated levels of liver enzymes, even when solvents and pesticides are present in the serum. This has also been reported in the literature with persons occupationally exposed to solvents.[133]

Serum tests for the presence of the most common, and most harmful, chlorinated pesticides, PCBs and solvents can prove invaluable. The publication of the CDC's National Reports has revitalized this area of laboratory medicine, because it provides national reference values for many of these compounds for the clinician. Before the publication of these data, the clinician had to rely on industrial-derived reference values or reference values from the pool of information that the laboratory itself had derived from its clients. For the biologically persistent PCBs and chlorinated pesticides, the CDC gives levels both in parts per billion and as lipid-adjusted (nanogram per gram lipid) values. These fat-soluble toxins are released from adipose tissue along with triglycerides and cholesterol.[134] Previously published research actually found that quantifying the fat-soluble xenobiotics according to the amount of lipids in the blood corresponded excellently with the amount of xenobiotics present in adipose biopsies of the same person.[135] Using the lipid adjusted values as a glimpse of the adipose burden of these compounds also allows the clinician to monitor the effectiveness of their depuration treatments. Follow-up testing would allow one to see if the body burden was decreasing.

Utilizing the CDC information that gives the 50th, 75th, 90th, and 95th percentiles for these toxins can also help the clinician to identify when the chlorinated pesticides or PCBs are from current exposure, rather than just being released from body stores. First, the clinician needs to find out the relation of the patients' parts per billion and nanogram per gram lipid values to the values given by the CDC. For example: the parts per billion value is very close to the 50th percentile, whereas the nanogram per gram lipid value appears to be somewhere between the 50th and the 75th percentiles. In any case where the serum level (parts per billion) appears to be in relation to CDC values that are less than or equal to that of the nanogram per gram lipid, it would indicate that the amount in the blood originated entirely from the adipose stores. If the level in the serum (parts per billion) was higher—around the value given for the 75th percentile—whereas the nanogram per gram lipid was below the CDC 50th percentile, then one could safely interpret that the patient had a current exposure to this toxin.

OP presence can be assessed by testing the urine for metabolites. Similar testing can be done for phthalate (plasticizers) metabolites, bisphenol A, and parabens. The presence of any of these metabolites in the urine would mean that the person was exposed to these compounds in the week before taking the urine sample. These tests can be highly useful in helping persons to attain a diet and lifestyle that are free from several serious toxic families.

Heavy metals can be measured in the hair, blood, urine, and stool. Blood levels are mostly indicative of current exposure levels and are still considered by many physicians to be the only valid method of heavy metal assessment. Unfortunately, the blood reference values for heavy metals are typically based upon industrial medicine standards for toxicity in the workplace. Fortunately, the CDC national reports again provide the national normal ranges for most of the heavy metals in blood and in urine (given as microgram per liter and microgram per gram creatinine). Utilizing both pre- and post-challenge urine tests for heavy metals can reveal if the patient is currently exposed and provide information on the appropriateness of the chosen heavy metal "chelating" agent.[136] When used with an oral chelating agent, doing a pre- and post-challenge test can also reveal information about the absorptive ability of the person (or lack thereof).[137]

TREATMENT METHODS

The basics of effective treatment for chemically-induced illnesses are avoidance of further exposures, supplementation to support chemical elimination and antioxidant protection mechanisms, and reduction of the body burden of xenobiotics.

1. **Avoidance of further chemical exposure.** This should not be overlooked, although it is often the most difficult step for compliance. In cases of multiple chemical sensitivity, this step is indispensable. By simply having a chemically-safe dwelling, many persons with chemical sensitivity begin to improve.[138] Compounds to be avoided include solvents, paints, exhaust fumes, perfumes, hair sprays, new furniture, carpeting, cabinetry, plastics, gas or oil heat, etc. Because the home is the environment

that is most in one's control, the home must be made a "safe oasis." If there are building materials that are off-gassing chemicals and these materials cannot be removed, they should be sealed. There are a number of good books available to help with these issues.*

The single greatest source of solvent exposure in the home comes from smoking inside, which also provides combustion by-products, cancer-causing chemicals, and heavy metals. After smoking, the next greatest sources are carpeting, new cabinetry, and new painting. Cleaning supplies, including tile cleaners, perfumes, air fresheners, and the presence of dry-cleaned clothing complete the rest of the top indoor polluters. Exposure to all of these can be reduced with simple lifestyle choices such as:

- Do not wear shoes indoors.
- Replace your furnace filters every 6 weeks with high quality pleated filters (rated Minimum Efficiency Reporting Value [MERV] 7-9).
- Air out dry cleaned clothing in the garage or car trunk for a week before bringing it into the house.
- Do not smoke indoors.
- Consider replacing your carpet with tile or stone flooring.
- Use nonscented laundry detergent and fabric softener.
- Consider getting an air purifier that has both charcoal and HEPA filters—(for example, IQAir and Blue Air). Make sure you get one with enough cubic feet of air purified each minute to clear the air in your bedroom at least once every 30 minutes.

In addition to avoiding environmental chemicals, any foods that cause adverse reactions should be avoided (see Chapter 15 on Food Allergies). Organic foods should be used wherever possible, as well as purified water. Avoiding the "dirty dozen" fruits and vegetables (www.foodnews.org), along with all farmed salmon, high mercury fish, and nonorganic dairy products will significantly reduce toxin exposures by food.

2. **Dietary support.** The best macro-diet choice (in addition to organic foods) is to consume a diet with high protein, low carbohydrate, and low fat. Such a diet helps Phase 1 biotransformation significantly.

Metabolism of toxic chemicals and drugs has been shown to be impaired by protein deprivation. Increased toxicity of chemical compounds and drugs has been reported with protein deficiency. Protein deficiency decreases the activity of liver mixed function oxidase (MFO) systems, which increases the half-life of numerous toxic chemicals and drugs and potentiates drug action and toxicity. The quantity and quality of protein in the diet alters both Phase 1 and Phase 2 reactions in drug metabolism (a gelatin diet induces very low MFO activity). The toxicity of organochlorinated compounds (OCCs), acetylcholinesterase inhibitors, herbicides, and fungicides have all been shown to be increased several-fold by protein deficiency. Reduced clearance of antipyrine and increased half-life of antipyrine have been found in Asian vegetarians with low dietary protein intake. This was not found in white vegetarians with adequate protein intake.

Although protein deficiency clearly reduces the ability of the body to adequately metabolize chemicals,[139] the opposite also appears to be true. Isocalorically increasing the ratio of dietary protein to carbohydrate ratio in well-nourished volunteers was shown to enhance clearance of antipyrine and theophylline. Although it was not clear if the effect of the protein was due to the amino acid content alone, it was known that methionine and cysteine deficiency led to reduction of intestinal and hepatic MFO enzyme activity. Hepatic MFO activity can also be suppressed by folic and choline deficiency. Low methionine intake also impacts selenium metabolism by making less selenium available for glutathione-peroxidase biosynthesis. High sugar intake is also known to reduce the clearance of certain chemicals from the liver.

Rice bran fiber (RBF), which can be found in a diet high in brown rice or using RBF as a fiber supplement, has been shown to have a high binding ability with PCBs and other toxins, including the combustion by-product benzo(a)pyrene in a laboratory setting.[140] When measured against other fibers, RBF demonstrated the ability to dramatically reduce the reabsorption (termed "hepatic recycling") of PCBs from the intestines in animals.[141] Hepatic recycling occurs after the liver dumps some of these toxins into the intestines with bile, but when these compounds make it to the small intestine, they are reabsorbed into the bloodstream and sent back to the liver. This recycling pattern is the main reason why such a minute amount of these toxins actually make it out of the body. Although RBF helps to break this recycling and gets more toxins to leave, wheat bran showed absolutely no benefit in this regard.[142] A study using either spinach fiber or RBF in animals that had been exposed to PCBs showed that RBF increased fecal PCB excretion 6.6 times and spinach fiber 4.1 times.[143] Another animal study showed that a 10% RBF diet increased the excretion of toxic furans 4.5 times that of placebo.[144] A few studies were done on a fermented RBF product that is available as a food item in Japan. PCB-burdened patients who consumed 7 to 10 grams of it three times daily (after each meal) for a year had twice the amount of dioxin excretion as their counterparts who did not consume that much fiber.[145]

Chlorophyll has long been thought of as a blood purifier and recent studies have documented its effectiveness at helping to clear persistent chemical pollutants from the body. As previously mentioned, both spinach fiber and matcha green tea increased the excretion of chlorinated persistent pollutants. Both of these compounds have chlorophyll, which may be a part of their effectiveness. The seaweed nori, which also contains chlorophyll, was tested in rats to measure its power at helping to clear dioxins. Rats fed a diet of 10% nori had an increase in fecal excretion of two different dioxins at levels 5.5 and 6.0 times more than the control group.[146] Chlorella, long a popular "detoxification" agent was also tried with dioxin-contaminated rats. The group of rats given chlorella had increased dioxin excretion that varied from 30% to over 300% higher than the control group.[147] Postulating that it was the chlorophyll content of the chlorella that was the active ingredient, this group of researchers then set out to measure that hypothesis.

The effectiveness of chlorophyll alone on the excretion of dioxins and furans from rats was quickly established. The higher the content of chlorophyll in the diet, the greater the excretion of these fat-soluble persistent toxins in the feces. The ranges of chlorophyll went from a low of 0.1% to a high of 0.5% in the diet. A diet with 0.1% chlorophyll is roughly equivalent to consuming 10% of your diet as spinach or 20% as seaweed. In the 0.1% group, the fecal excretion of the various toxins ranged from 40% to 80% greater than the control group. At the end of the study, all of the animals that were given chlorophyll had a lower total body burden of these persistent toxins than their counterparts.[148]

Because chlorophyll turned out to be the active agent in binding some of these toxic pollutants and increasing their levels in the stool, the next step was to check how well chlorophyll-containing

*Three good books on this subject are *Less Toxic Living* by Carolyn P. Gorman, available from Environmental Health Center-Dallas (214) 368-4132; *Success in the Clean Bedroom* by Natalie Golos, Pinnacle Publishers, Rochester, NY; and *Your Home, Your Health, Your Well-Being* by David Rousseau, published by Hartley and Marks, Vancouver, BC, Canada.

vegetables did in lowering toxic burden. In this study, rats were fed either a diet with or without 10% vegetables. As with the previous study, the higher the level of chlorophyll in the vegetables, the higher the rate of excretion of the toxins.[149] The vegetables with the smallest increase in fecal dioxin excretion (60% to 300% increase) were Chinese cabbage, broccoli, onion, Welsh onion, cabbage, and celery. The vegetables with the next highest dioxin excretion (330 to 480% increase) were kale, Chinese chive, Shungiku, Chingensai, green lettuce, and sweet peppers. The group that topped the charts with an increased dioxin excretion of 760% to 1160% were: Komatsuna, mitsuba, spinach, and perilla. So, here again we have spinach topping the charts. However, because spinach is 1 of the top 12 most toxic vegetables, one would need to find organic spinach or use some other form of chlorophyll. The same can be said for seaweeds' toxin mobilizing ability, which has been previously discussed. Seaweeds have been found to be highly contaminated with heavy metals and, therefore, are not a good addition to diet or health plans.

3. **Nutritional supplementation.** In cases of toxic overload, supplementation can be tricky, as some persons with severe chemical reactivity can react to many of the nutrients that are normally needed. In his four-volume treatise on *Chemical Sensitivity*, Rea stated that his chemically burdened patients were typically deficient in magnesium, selenium, and Vitamin B_6 (whether or not they were taking oral supplements of these).[5] Supplementation with high levels of antioxidants is typically recommended because all of these xenobiotics have been shown to cause oxidative damage.
4. **Depuration (cleansing).** The removal of impurities from the body is known as depuration. This is the preferred term for cleansing xenobiotics from the body. Besides all of the literature about the use of RBF and chlorophyll for depuration, two additional methods have been discussed in the scientific literature: fasting and sauna.

Most of the published literature is from one of the Health Med clinics associated with the Church of Scientology, which performs the "Hubbard Purification Rundown." This protocol utilizes exercise, high temperature saunas, increasing doses of niacin, and electrolyte replacement. They published studies showing the benefit of this protocol for reducing levels of PCBs, polybrominated biphenyls (PBBs), and hexachlorobenzenes.[150-152] Their studies, along with unpublished information from Environmental Health Center, Dallas (EHC-D), with William Rea, MD, showed that sauna therapy reduces xenobiotic levels in treated individuals.

The only published treatment besides sauna therapy that has shown benefit in treating poisoned individuals is fasting. This has been documented in a single study that examined individuals poisoned by PBB contaminated rice bran cooking oil in Taiwan.[153] Although fasting reduced their symptoms, it increased the level of circulating xenobiotics in their serum. Presumably the elevation of circulating toxins was due to the increased rate of lipolysis in fasting individuals. Thus, the fat soluble PBBs were released from storage into the bloodstream in higher than normal rates. At that point it, would have been up to the liver to clear these out of the serum or they would have been redeposited into the adipose tissue. More research is obviously needed on the role of fasting in the treatment of environmental overload.

A comprehensive naturopathic protocol for treating environmentally poisoned individuals was developed by the author and has been in use for over 10 years. An outcome study on persons who underwent this protocol for a variety of chemically-induced ills revealed it to be surprisingly effective. Of all the various problems treated with the depuration protocol, 83% of the participants rated their results as good or great. The two conditions in which 100% of the participants reported great results were asthma (n = 3), and addiction recovery (n = 1). There were several problem (chief complaint) categories in which 100% of the participants rated their results as moderate/good or great. Those categories were autoimmune, dermatologic, and gastrointestinal, and/or liver. The categories with the next highest ratings of moderate/good and great were fatigue with 92% improvement, allergies with 85%, and chemical sensitivities with 84% improvement.[154]

The Crinnion Depuration Protocol

The Crinnion Depuration Protocol consists of the following components:

1. **Daily exercise.** Exercise usually consists of using an exercycle, rebounder, or brisk walking to begin lipolysis and diaphoresis.
2. **Thermal chambers**. Up to 36 minute "sauna" sessions are done with temperatures at a range of 120°F to 135°F with cool-down periods in between. Glass bottled spring water is given along with electrolyte replacement. Although the Hubbard clinics use higher temperatures, we found that individuals will put out more toxins (as evidenced by stronger chemical odors), and will have less adverse symptoms when lower temperatures are used. The thermal chambers will increase the rate of lipolysis in the adipose tissue throughout the body. When this occurs, the lipophilic xenobiotics will be released into the bloodstream. Those compounds in the subcutaneous fat pads will be mobilized through sweat as well as into the blood.
3. **Constitutional hydrotherapy.** This uses alternating hot and cold towels with sine wave stimulation as done by Drs. O.G. Carrol and Harold Dick. This therapy has been used for decades to stimulate the body's own self-healing activity. We found that it also increased the amount of toxin-laden bile dumped from the liver into the intestines. Also assisting the choleretic and cholagogue action on the liver is an herbal capsule taken daily consisting of *Chelidonium*, *Chionanthus*, *Taraxacum*, *Arctium lappa*, *Silybum mar.*, and *Urtica dioca*.
4. **Colonic irrigation.** Gravity fed machines are used to gently introduce triple-filtered water into the large intestines, providing an avenue for toxic bile to rapidly leave the body. Individuals will routinely have "liver dumps" of bile that range in color from yellow to red, with occasional gray or brown. The color of bile normally ranges from green to yellow to orange to red depending upon the amount of time of exposure to bacterial action in the bowel. However, in this situation we believe that it is dumped from the liver and rapidly passed through the small intestines, similar to what is seen in "gastric dumping" syndrome. We are therefore unable to account for the differences in color of this effluent. In some patients with heavy agricultural exposure, we have seen higher amounts of fluorescent yellow bile. Hence, the color of the bile may be more attributable to the chemical compounds in the bile than the bacterial action upon the bile. We have documented that chlorinated pesticides are present in the effluent, which we refer to as "bile dumps."
5. **Constitutional homeopathy.** This has been used primarily as a stand-alone treatment with the use of any other supplemental and treatments prohibited. However, we have found it to be a valuable component of this protocol and completely compatible with all the other treatment methods involved. It appears most beneficial in those individuals who need a boost for their vital force to get them moving toward healing, and for those who are stuck in emotional issues that they have not been willing to look at.

6. **Body therapies (massage, Shiatsu, craniosacral, visceral, chiropractic).** These are done as needed for the individual to treat specific musculoskeletal problems and to assist in mobilizing toxins that are stored in the tissues.
7. **Counseling.** Mental and emotional toxins are as big a problem as physical and/or chemical toxins. When people are exposed to powerful emotional toxins (abuse, etc.) that they have no outlet for handling, they end up "stuffing" the emotional toxins. When this emotional stuffing occurs, any physical toxins that they are exposed to at that time are also stuffed (stored) rather than being eliminated. Because of this, when they start to mobilize the physical toxins, the old emotional issues will come back into consciousness. When individuals choose to again suppress the emotional issues (rather than facing them), their physical cleansing will also stop. This is evidenced by the observations that they will stop sweating in the thermal chambers, stop heating the cold towels in the hydrotherapy, and stop having good liver releases in the colonic therapy. When the emotional "toxins" are faced and released, then these cleansing parameters are returned to former levels. Assisting all of the individuals going through this depuration protocol with their emotional issues helps them to cleanse physically.

This protocol is run on a daily basis that usually lasts between 4 and 8 weeks (5 sessions weekly). This protocol begins the depuration process, which then must be continued once the individual returns home. Most individuals will need to continue regular cleansing (use of home saunas, hydrotherapy, and colontherapy) for at least 12 months after completing their intensive in-office cleansing. When testing for serum levels of chlorinated pesticides, PCBs, and solvents is repeated along with immune parameters after 12 months, improvements are routinely seen. In addition to symptomatic relief, improvements in the laboratory reports (decrease in serum xenobiotics and reduction in autoantibodies, etc.) is clearly evident.

SUMMARY

Environmental chemicals are ubiquitous in our environment and in our bodies. Damage by these xenobiotics can be found in virtually every cell, tissue, and organ system in the human body. However, the main targets appear to be the immune, neurologic, and hormonal systems. Many of the chronic health problems caused by toxins in these systems often present as classic problems that are considered to be the result of aging. Classic immunotoxicity manifestations include the development of allergies and asthma, chemical reactivity, chronic infections, and autoimmunity. Neurotoxicity typically presents with decreased cognition, headache, fatigue, short-term memory loss, and mood disorders. Endocrine toxicity can result in hypothyroidism, obesity, infertility, and diabetes.

Exposure to many of the ubiquitous xenobiotic toxicants can be easily eliminated by simple lifestyle choices (Box 35-3), although the burden of fat-stored pollutants can be reduced by depuration techniques that often can be handled through dietary changes. The diagnosis of xenobiotic-induced damage can be elucidated by a comprehensive history, along with evidence of serum toxin levels and toxin-induced immune system damage.

BOX 35-3 Treatment

Avoiding toxic exposures is mostly in one's control

Diet and home air:

1. Avoid the 12 most toxic fruits and vegetables (peaches, apples, bell peppers, celery, blueberries, kale, nectarines, strawberries, cherries, pears, imported grapes, spinach, lettuce, potatoes); use organic varieties of these instead.
2. Freely eat all of the 15 least toxic fruits and vegetables (onions, avocado, sweet corn, pineapples, mango, asparagus, sweet peas, kiwi fruit, cabbage, eggplant, cantaloupe, watermelon, grapefruit, sweet potato, honeydew melon).
3. Do not eat any farmed or Atlantic salmon
4. Freely eat Alaskan salmon (available fresh only from June until October); canned and frozen Alaskan Salmon available year round.
 a. Alaskan/Pacific salmon will always be labeled as King (Chinook), Red (Sockeye), or Silver (Coho) Salmon. If that distinction is not given, it is farmed salmon being passed off as Alaskan.
5. Avoid the fish with the highest mercury content (shark, swordfish, king mackerel, tuna, orange roughy, marlin, Chilean bass, lobster, halibut, snapper).
6. Freely eat the fish with the lowest mercury content (clam, Ocean perch, Alaskan salmon, tilapia, flounder, sole, catfish).
7. Avoid all sugar—sugar reduces the ability of the liver to clear toxic compounds out of the bloodstream.
8. Begin to reduce the toxicity of the air inside the home:
 a. Don't wear shoes indoors.
 b. Replace the furnace filters every 6 weeks with high quality pleated filters (rated MERV 7-9).
 c. Air out dry-cleaned clothing in the garage or car trunk for a week before bringing them into the house.
 d. Do not smoke indoors.
 e. Consider replacing the carpet with tile or stone flooring.
 f. Use nonscented laundry detergent and Bounce.
 g. Consider getting an air purifier—the best are IQAir and Blue Air. Make sure you get one with enough cubic feet of air purified each minute to clear the air in your bedroom at least once every 30 minutes.
 h. Follow the directions for step-by-step reduction of indoor air pollution sources in *Clean, Green and Lean* (Wiley, Publisher)

Dietary things to do:

1. Consume broccoli and the other members of the brassica family daily.
2. Consume green tea daily.
3. Increase levels of green foods (green leafy veggies) daily.
4. Consume brown rice daily, or take a rice-fiber supplement.

Basic supplementation:

1. Multivitamin/multimineral—take a quality product daily
2. Vitamin C—begin with 3000 mg/day, for cases of high toxicity, a total of at least 9000 mg/day may be needed (unless this causes diarrhea).
3. *N*-acetyl cysteine—1500 to 1800 mg/day. This nutrient helps to increase the amount of glutathione in the body.
4. Magnesium citrate—1 capsule (140 mg) up to three times daily.
5. A good probiotic—1/day.
6. Rice bran fiber—1 tablespoon in water or juice after each meal.
7. Whey protein powder—2 scoops daily in water or organic juice—high quality whey protein will help boost glutathione level and increase the ability of the liver to clear toxins out of the blood.

Cleansing:

1. Begin doing colonic irrigations. This is the best way to reduce the total toxic burden. It works best to do five colonics in the first 2 weeks, which will typically reduce the circulating toxic load enough for both the patient and the clinician to notice the difference.

CHAPTER 36

The Exercise Prescription

Jade Teta, ND, CSCS, and Keoni Teta, ND, LAc, CSCS

INTRODUCTION

Movement has been inextricably linked to health, well-being, and survival throughout human existence. It served as the means to procure food and was the key tool in protecting ourselves in times of danger. The ability to fight, flee, migrate, and forage was at the very core of life. Today, movement is no longer required for survival, and food is easily available with little need to expend energy. Yet the ancient connection between movement and metabolism remains permanently imprinted into our physiologic function. Combating the diseases of the modern day is impossible without restoring movement as a permanent way of life.

Because a full discussion of movement and exercise physiology is beyond the scope of this chapter, this chapter will instead focus on movement as medicine for the most common diseases, with special focus on the overlapping mechanisms that account for exercise's beneficial impact. A strong emphasis will be given to newer understandings of exercise physiology and metabolism and how this information relates to the practice of medicine as well as the historical human condition.

The obesity epidemic, by most estimates, is the greatest health challenge of this century. It already represents one of the largest modifiable risk factors for increased morbidity and mortality, with close to 66% of the U.S. population overweight or obese.[1,2] Because of the huge challenges obesity represents, and the powerful role exercise can play, this chapter will be framed in the context of weight management. Other related health issues, such as exercise approaches for inflammation, cardiovascular disease, cancer, mood, and the brain, will also be discussed.

EXERCISE IN HISTORICAL CONTEXT

Human movement patterns have always necessitated multiple parameters of fitness. Understanding these historical movement patterns provides guiding context in which to view exercise. Although research in exercise is essential to understand, without a guiding context it can be difficult to provide appropriate exercise prescription. Viewing movement through the lens of human evolution, we believe, provides the frame of reference necessary to understand how to use movement as medicine.

Longer duration lower intensity exercise made up the majority of early human activity.[3-5] Walking was the chief means of movement for millions of years. Early humans walked most of the day and did this everyday. Their survival was dependent on it. Research suggests that early Homo sapiens foraging on the plains of Africa covered a range of over 10 miles daily hauling weapons, game, and tools.[3-6] Analysis of modern day hunter–gatherers confirms this degree of walking activity.

In addition to this lower intensity activity, survival also depended on higher intensity shorter duration activity. Sprinting away from danger or after wild game as well as lifting and hauling were essential. Both women and men engaged in these more anaerobic bouts of exercise. Although in most cultures women did not participate in the hunt, they did lift and haul wood, help construct shelters, and carry babies. The average baby was carried almost 1000 miles in the first 2 years of life in more traditional cultures.[4] The more intense activities of hunting, hauling, and foraging were done in what is termed the "paleolithic rhythm," where more intense activities were spaced out over 2 to 4 nonconsecutive days per week.[4,6]

Moderate intensity exercise, much like aerobic exercise today, was also a part of life. However, this exercise did not take the shape of going for a jog or leisure run.

Aerobic exercise was mostly in the form of sporadic running after food and dancing, which occupied an important place in the culture of ancient peoples and still does in modern day hunter–gatherer societies. These dances can last from one to a few hours and take place several times during the week.[4-6]

The movement patterns of our historical ancestors were a necessary part of life and were fully integrated into the lifestyle. This movement was what could be best described as "cross-training," with elements of lifting, jumping, running, walking, throwing, climbing, hauling, hiking, or whatever movement pattern was required to procure food, stay protected from the elements, and defend territory. Our species is adapted from an environment where food was not guaranteed and a nomadic hunter–gatherer way of living dominated. This understanding is essential for the appropriate prescription of exercise. Hunter–gatherer societies in the past and present have been analyzed through a number of different scientific tools, which show that they do not experience the same degenerative and chronic diseases of modern westernized peoples.[3,7,8]

After taking into account body weight, the modern day human energy expenditure is estimated to be only 38% that of our hunter–gatherer ancestors.[4] It has been shown that for modern day humans to approximate the level of activity of hunter–gatherers, they would have to walk 12 miles/day in addition to other activity.[4] Policy leaders on appropriate levels of human activity, such as the American College of Sports Medicine, recommend movement patterns estimated to be 44% less than that of our prehistoric ancestors and modern day hunter–gatherers.[4]

Several studies have shown that total energy consumption from exercise may be the primary health promoting property of movement.[4,9,10] Given the drastically different environment in which humans now reside, we are left with a serious dilemma. How do we get people to do an activity not required for their survival, that takes time, and is not an enjoyable activity for many? It is useful to remember that the number one reason given for not participating in exercise is time.[11,12] These facts, as well as the historical frame of reference provided by evolutionary movement patterns, create a problem. Exercise prescriptions must deliver acceptable caloric expenditure, should mimic the cross-training attributes of our ancestors, but also be time conscious and "doable" for the average population.

A NEW PERSPECTIVE ON MOVEMENT

It is easy to look at the data presented and quickly move to a "more is better" approach to exercise. However, movement quality is an important consideration before simply instructing more exercise. Quality in this segment is discussed in terms of more functional and efficient movement. In other words, movement that provides the perfect balance of range of motion and stability leads to more efficient animation of the body. The body is a chain of parts that are completely integrated. Individual exercises, although viewed in isolation by us, are actually complex and highly entrained patterns of neurologic connections translated into muscular action. These "movement patterns" are the building blocks on which all exercise is constructed. Without a strong foundation, the benefits of exercise can sometimes become a liability, increasing the risk of injury, pain, and dysfunction.

It is both irresponsible and shortsighted to focus exercise prescriptions solely on delivering greater metabolic stimulus if there is not a strong and appropriate base of mobility and stability through basic movement patterns. In other words, doing more activity may not be beneficial if it simply reinforces poor movement mechanics. We must keep in mind that our ancestors were able to move more, because they also moved better.

Human development and survival from infancy to adulthood required mastery of movement. The neurologic and muscular systems are built as a unit and cannot be separated. Movement should not be thought of in terms of isolated anatomy but rather as an integrated system that moves in patterns. A squat, for example, is not simply a matter of contracting certain muscles that move joints. It is instead a coded and rehearsed pattern of neurologic firing translated into physical movement.

Gray Cook, physical therapist and the foremost expert on functional movement, is the author of two of the most foundational pieces of work in movement science. In his books, *Athletic Body in Balance: Optimal Movement Skills* and *Conditioning for Performance* and *Movement: Functional Movement Systems*, Cook described movement science as analogous to the relationship between computer software and hardware.[13,14] The muscles and joints act as the hardware, but the neuromuscular firing pattern is the software. Software obviously is what controls and informs the computer, and so it is with the nervous system controlling the muscle. To address movement, he rightly pointed out that we need to work movement patterns and not simply isolate parts.

The brain does not view exercise as individual muscles working. Instead, the brain has a code or a pattern for each movement. This pattern consists of thousands of different neurons firing in very specific ways to elicit a coordinated action, resulting in a movement. Each movement is to the brain like a computer software program; movement science calls this a motor program. It is these motor programs that need to be attended to in terms of movement quality.

Although exercise science has developed core principles and protocols to be followed, movement has not developed such protocols. Up until very recently, there has been no standardized understanding of what constitutes normal functional movement. This gap has now been filled by the work of Gray Cook and his colleagues. They have put together a system of screening and analyzing movement so it can be objectively measured, tracked, and corrected. If we are to use movement as medicine and stay true to the natural medicine axiom of "first, do no harm," we must establish a standard of practice in movement medicine.

STANDARDS OF MOVEMENT

The Functional Movement Screen and Selective Functional Movement Assessment

The Functional Movement Screen, or FMS, as it is popularly known, is "a ranking and grading system that documents movement patterns that are key to normal function." By acting as a screen for movement, the FMS pinpoints movement dysfunctions that may predispose to injury and/or inefficiency.

The FMS has a scoring system that allows for a hierarchical ranking of the most limiting patterns or asymmetries unique to an individual. This in turn provides direction to clinicians as to what corrective strategies should be implemented and when. The FMS score can then be used to systematically address underlying movement dysfunctions and restore a base of movement from which conditioning can be built.

The FMS is complimented by the Selective Functional Movement Assessment (SFMA). The SFMA is the diagnostic system of functional movement. For the clinician concerned with movement, the two work hand-in-hand. The FMS is both the precursor to and the follow-up from the SFMA. The FMS looks at seven key movement patterns, including a squat, lunge, and hurdle step. Its purpose is to ascertain a baseline of mobility and stability as well

as to determine if movement is pain free. The SFMA is the clinician's tool for diagnostic determination of when pain is present. Together, the screen and the assessment provide a movement system that allows tailored movement plans that can find, address, and track changes in movement from pain and dysfunction to recovery and optimal movement.

The FMS is a screening tool for the clinician; it is not diagnostic, but rather prognostic. The SFMA is diagnostic and helps the clinician pinpoint the issue and further prioritize treatment. Once a patient has been discharged from treatment and no longer has pain with movement, movement quality must still be measured. This is where again the FMS is used.

Several recent studies showed the FMS to be a reliable and repeatable screening tool for movement quality, but also proved its ability to predict injury in several high population groups. Minick et al[15] showed that the FMS demonstrated substantial inter-rater reliability by both novice and expert users. This demonstrates an important quality of any clinical tool, that of repeatability and objective evaluation in the hands of different users.

When the FMS was put to the test in very active population groups its usefulness became clear. American football players were analyzed in a 2009 study in the *Scandinavian Journal of Medicine, Science and Sports*; they demonstrated reliable improvements in FMS scores from a standardized intervention based on the screening examination and established a FMS score cutoff predictive of increased injuries.[16]

Firefighters benefitted from a FMS guided functional exercise program.[16a] The FMS guided intervention resulted in a 62% reduction in time off of work due to injuries and reduced injuries by 42% during a 12-month period.

Movement pattern performance is an important precursor to increased exercise participation and is an important addition to the exercise world. The FMS and SFMA are new and essential tools for the use of exercise as medicine. They provide a much needed "standard operating procedure" for movement quality. Gray Cook and colleagues have a clinical website (www.functionalmovement.com) that teaches and instructs on movement systems and provides valuable clinical tools for clinicians.

NEW INSIGHTS ON EXERCISE FOR WEIGHT LOSS

Once movement quality is attended to, exercise quality needs to be addressed. The current approaches of exercise for weight loss and health are still centered in the low intensity "aerobic zone," calorie-burning paradigms. Recent understanding is redefining this narrow approach to health and fitness. A caloric focused model of metabolism may not be the most useful way to view exercise. If we look at track athletes, both elite marathoners and sprinters have very low percentages of body fat. Sprinters, however, have less body fat and higher amounts of muscle mass, yet they exercise in a very different way.[17-19] Sprinters engage in short bursts of anaerobic effort lasting seconds, whereas marathoners run in an "aerobic zone" for hours and utilize large amounts of caloric energy. If the aerobic model of exercise truly is the best way to gain fitness and fat loss, why is there a discrepancy between these two groups of athletes? In analyzing recent data, we can see that anaerobic contributions to energy expenditure now need to be considered in exercise prescription.

There is a common misunderstanding of fat burning percentages in exercise. Many still perceive exercise done in the aerobic zone, usually defined as between 65% and 80% of maximum heart rate (MHR), burns the most fat per unit time. This is not the case. Lower exercise intensities burn a higher proportion of fat compared with sugar, relatively speaking. However, exercise beyond the aerobic training zone burns more total energy and fat because it is a higher intensity.

Suppose two people exercise for 30 minutes. Person A jogs at an intensity of 60% MHR, whereas person B jogs at an intensity of 60% MHR and then, every few minutes, sprints for a short period, reaching over 90% MHR before returning to a lower intensity. Assume person A burned 200 calories, 60% coming from fat and 40% from sugar. Person A therefore used 120 total units of fat and 80 units of sugar (200 calories × 0.60 = 120 fat calories). Person B exercised at a higher intensity, burning a lower percentage of fat. Assume Person B used 50% fat and 50% sugar, but burned 100 more calories due to the higher workload. Person B therefore burned 150 units of fat and 150 units of sugar (300 × 0.50 = 150 fat calories). When the energy burned is totaled, person B burns more energy (300 calories) and more total fat (150 units compared with 120 units) than person A, despite using a lower percentage of the energy as fat. This example shows that higher intensity exercise of the same duration surpasses lower intensity exercise in fat calorie use. There are further metabolic consequences created through higher intensity exercise that make its application in exercise prescription for fitness and fat loss more intriguing.

Does Aerobic Exercise Work for Weight Loss?

A 2009 review by Melanson et al[20] looked at the impact exercise had on metabolic stimulation. The study primarily looked at moderate intensity aerobic exercises like jogging, biking, or swimming while including a small sample of anaerobic exercise studies. It showed that aerobic exercise of moderate intensity did not provide a metabolic advantage aside from the calories burned during activity. A previous meta-analysis done over a 25-year period came to a similar conclusion.[21] This study analyzed the data from over 400 studies comparing diet alone, aerobic exercise alone, or diet plus aerobic exercise on weight loss. The results showed that aerobic exercise did not provide a significant advantage to weight loss over diet by itself. Although aerobic exercise has been shown to be a reliable tool in the maintenance of weight loss,[22,23] these studies suggest it may not be enough to elicit significant fat loss effects.[21]

At the same time, new lines of research show potentially promising effects from more anaerobic modalities. High-intensity interval training (HIIT) is a method of alternating highly anaerobic activity with more relaxed aerobic movement. This method allows the benefits of intense exertion under more tolerable conditions. Rest is required to sustain intense activity for any length of time. Weight training is another anaerobic-centered activity. These more anaerobic-dominated exercise approaches have unique benefits that may compliment the calorie burning effects of aerobic exercise.

Aerobic Versus Anaerobic Exercise

In very simple terms, aerobic metabolism takes place in the mitochondria and requires the use of oxygen. Anaerobic metabolism proceeds through a different pathway and requires neither the involvement of mitochondria or oxygen. It is well known that as exercise intensity increases, anaerobic metabolism dominates; unfortunately, the exact anaerobic contribution to energy production is exceedingly difficult to measure. The standard way to approximate calorie expenditure and substrate utilization during exercise is through the measure of respiratory gases. The ratio of carbon dioxide expelled to oxygen consumed can give a predictable evaluation of not only energy use but also fuel utilization—glucose versus fat.

However, this method is only valid at lower exercise intensities. At higher intensities, the relationship is less clear. To help address this error, researchers also measure excess postexercise oxygen consumption (EPOC). This is a measure of the recovery energy expenditure after exercise and it has been thought to consist of anaerobic contributions to exercise as well. There is some argument as to how meaningful this EPOC effect can be. Many researchers claim the impact does not last long, only several hours, and amounts to at best 15% of total calories burned.[24-26] However, these approximations come largely from studies with lower exercise intensities involving standard aerobic exercise protocols.

Studies utilizing highly anaerobic protocols including cardiovascular interval protocols and weight training showed a much different picture. In 2001, Schuenke et al[27] showed that circuit resistance training, utilizing heavy weights and short rest periods lasting only 31 minutes, were able to generate an EPOC that persisted for 48 hours. The results showed that metabolism 24 and 48 hours after the exercise session was increased by 21% and 19%, respectively. The researchers pointed out that for a typical 180-lb individual "this equates to 773 calories expended post exercise" while resting and as a result of the workout. This is far from insignificant and greatly exceeds the 15% many researchers quote for EPOC. Similar findings were shown in women using a similar resistance training protocol. In women, the elevation in metabolic rate lasted 16 hours.[28] The same findings were seen with HIIT protocols with significant EPOC values lasting up to 24 hours.[29,30]

Exercise Burn and "After-Burn"

Dr. Christopher Scott of the University of Southern Maine published extensively in this area and is the author of one of the authoritative textbooks in this field, *A Primer for Exercise and Nutritional Sciences: Thermodynamics, Bioenergetics, and Metabolism*.[31] In his works, Dr. Scott pointed out that EPOC did not fully explain anaerobic energy use and that the anaerobic contributions to exercise might be even greater than originally thought, especially where lactic acid production is concerned. Dr. Scott emphasized that to fully account for calories burned during exercise, three components must be measured: (1) calories burned aerobically during exercise, (2) calories burned aerobically after exercise (EPOC), and (3) anaerobic calories burned from exercise.[32-36] EPOC and the anaerobic lactic acid measurements for exercise should be considered separately according to Dr. Scott.

A 2005 study by Dr. Scott demonstrated the potential ramifications of anaerobic exercise. This study compared a 3.5-minute aerobic exercise challenge with 3 work-equivalent 15-second sprints.[37] Calorie use during the exercise bout was calculated to be 29 kcal for the aerobic exercise and approximately 4 kcal for the sprinting. However, when the EPOC contribution was added to the two exercise bouts, energy use rose to 36 kcal for the aerobic bout and 39 kcal for the sprint exercise. Finally, when the purely anaerobic contribution was added to the calorie totals, the numbers for the anaerobic sprint exercise rose significantly. The final tally was 39 kcal for the aerobic exercise compared with 65 kcal for the sprint exercise. By adding both EPOC and the anaerobic contribution to the original calorie total, the sprint exercise was shown to far surpass the aerobic exercise in calories burned. This is interesting when one considers the aerobic exercise session took over four times longer to complete (210 vs 45 seconds). Without including both the EPOC and anaerobic energy use, a full 94% of the calories used during the sprinting would go uncounted.

In studies published in 2006 and 2009 in the *Journal of Strength and Conditioning Research*, the same researchers quantified anaerobic energy use during weight lifting.[32,36] Using the method of measuring and quantifying all three components of calorie burn (aerobic metabolism during exercise, EPOC, and anaerobic contributions), these studies showed that weight training exercise burned 70% more calories than originally thought.

Hormonal Versus Caloric Exercise

To understand the full ramifications of this new exercise science, the discussion must move to hormonal metabolism. Hormones as we describe them in this chapter refer to all signaling molecules in the body, including steroid hormones, muscle-derived cytokines (myokines), and other signaling molecules. Hormonal messengers directly influence the fat burning stimulus during exercise and may be responsible for part of the EPOC after-burn as well.

Brief bouts of anaerobic exercise appear to adjust hormones for greater caloric burn during and after exercise.[38] This increased energy use is partly explained by EPOC. This is a measure of how much oxygen the body consumes in the hours and days after a workout. An example of EPOC in the acute sense is climbing a long flight of stairs. While walking up the stairs breathing is labored, but respiration becomes most difficult after reaching the top. The body does this to recover the "debt" of oxygen used during activity. The EPOC created by climbing a flight of steps is an example of the much larger metabolic effect created from intense movement.

Exercise of sufficient intensity elevates stress hormones like adrenaline, noradrenaline, and cortisol. Together these hormones ensure the switch to glucose metabolism, which historically supplied the energy to fight or flee. As exercise intensity is elevated further, anaerobic contributions to metabolism increase. This produces lactate (lactic acid), which, contrary to common belief, is not a waste product, but a physiologic buffer and signaling molecule.[39-41] As lactate rises, it is correlated with, and some studies suggest actually induces, the anabolic steroids testosterone and human growth hormone (HGH).[42-44] This "hormonal soup," catecholamines along with cortisol, HGH, and testosterone, acts synergistically to increase postexercise fat loss and lean muscle tissue production, thus creating a more fit and functional physiology.

Aerobic and anaerobic exercise have different hormonal effects. Hormones do not work in isolation, and like people they behave differently depending on the social environment. Interestingly, the hormone cortisol, often seen as a fat storing hormone due to its insulin desensitizing effect, behaves differently when combined with growth hormone and testosterone.[41,45,46] When cortisol is "socializing" with testosterone and growth hormone, its catabolic action on muscle is blocked, fat storing at the belly is attenuated, and the three may synergistically enhance fat burning.[46-49] Attempting to blunt the cortisol response to high intensity exercise may be counterproductive for fat burning and not necessary in the context of growth hormones.[50-54]

Long duration lower intensity cardiovascular exercise behaves differently in regards to cortisol. There are also key changes in hunger hormones that are different between lower intensity aerobic exercises compared with higher intensity anaerobic workouts. With aerobic zone exercise, there is a danger of cortisol increasing unopposed by the growth promoting hormones.[45] This, along with a lowering of leptin and an increase in ghrelin, can lead to compensatory eating with specific cravings for fatty, sugary, and salty foods.[55-61] Higher intensity shorter duration activity has the opposite impact on ghrelin, with a more balanced ratio of catabolic versus anabolic hormones.[58,59] This may explain

why standard aerobic prescriptions have not been shown to be as effective for optimal body composition.[20,21,62-65]

Aerobic Zone Versus Interval Training

A 2001 study compared standard aerobic zone training and anaerobic interval exercise in women.[66] The anaerobic interval group exercised for 2 minutes at a highly intense 97% of MHR. They then rested by doing 3 minutes of low intensity activity. The more aerobic group performed moderately intense activity at close to 70% of MHR. The researchers made sure that each group burned 300 calories. Despite exercising longer and burning the same amount of calories, the aerobic group lost less body fat at the end of the study compared with the interval group. In addition, fitness in the interval group was substantially greater than in the aerobic group.

A similar study published in the same journal in 1996 showed that an anaerobic trained interval group burned significantly more fat than their aerobically trained counterparts.[67] Not only did the interval group burn greater amounts of fat during exercise, but they also exhibited increased fat burning effects that persisted for 24 hours after the exercise had stopped. The interval group was able to accomplish this with an exercise session that was a full 15 minutes shorter than the aerobic group.

A 1994 study[68] tracked two groups of people, one group doing aerobic training for a period of 20 weeks, whereas a second group was followed for 15 weeks and engaged in HIIT. The researchers wanted to see how each program would impact body composition. The aerobic group burned 48% more calories than the interval group (120.4 vs 57.9 MJ) during exercise. The interval group, however, enjoyed a ninefold greater loss in subcutaneous fat. At the conclusion of the study, muscle biopsy analysis showed resting levels of 3-hydroxyacyl coenzyme A dehydrogenase, a marker of fatty acid oxidation, were significantly elevated in the interval group, but not in the aerobic group.

A 2008 study looked at intense intermittent exercise compared with steady-state aerobics.[69] Forty-five healthy women between the ages of 18 and 30 were recruited for the study, divided into 3 groups, and studied for 15 weeks. One group did HIIT, where they sprinted on a bike for 8 seconds followed by a 12-second rest. This was repeated for 20 minutes. Another group did moderately intense peddling that was sustained for 40 minutes. The final group did no exercise. At the end of the 15 weeks, the high intensity interval group lost 2.5 lbs of fat, whereas the aerobic group actually gained 0.6 lbs of fat. A measure of the fat-related hormones leptin and insulin were also positively affected in the HIIT group compared with the steady-state group. This was accomplished with a workout that was half as long (20 vs 40 minutes) as the steady-state's group.

Resistance Training Studies

Research hints that resistance training may also provide unique benefits for fat loss and fitness. Recent analyses showed that the clear distinctions once set for aerobic exercise and resistance training are no longer delineated so clearly. Circuit training routines have been shown to provide an aerobic stimulus great enough for cardiovascular benefit while providing strength-training benefits.[70,71] Resistance training may also have great applicability for not just fitness and fat loss but also diseases of insulin resistance.[72,73] Weight training, compared with aerobic exercise, greatly attenuates the natural loss of muscle mass that occurs with aging and dieting,[74] and improves body composition and self-esteem better than aerobic exercise modalities.[75-77]

Resistance training may also have a much greater impact on EPOC. Two studies already discussed[28] showed significant metabolic elevations in men lasting up to 48 hours and in women lasting up to 16 hours. These workouts used exercise regimens that were more intense than most studied resistance-training programs, but they were also shorter. Combining the benefits of resistance training with cardiovascular exercise seems to have the most benefit.[78] This type of training is called concurrent exercise and involves resistance-training workouts that are followed immediately by aerobic exercise or vice versa. Studies showed that these approaches afforded the benefits of both aerobic and resistance-training workouts.[79-82] This "cross-training" approach falls in line with historic movement patterns and saves time.

Concurrent exercise approaches follow two patterns, serial concurrent exercise (SCE) and integrated concurrent exercise (ICE). In SCE, the two modalities (aerobic and resistance training) are done one right after the other, whereas in the integrated format the two modalities are alternated; a weight training movement is done followed by a cardiovascular "burst" of exercise. Based on studies, it appears the benefits of this type of approach can be amplified further using the ICE approach. In a series of three studies in 2008, all published in the *Journal of Strength and Conditioning Research*, Davis et al[83-85] showed the potential benefit of ICE protocols. An ICE workout consisted of brief 60 second bursts of "cardioacceleration" placed between traditional weight training sets. This protocol was able to dramatically amplify multiple fitness parameters over and above the same workout volume done in an SCE format.[84] Fat loss in the ICE group was close to 10 times greater than in the SCE group over an 11-week period. This constituted a time commitment of just over 4 h/week. Because the work was equivalent in both groups, it was the combination of exercises that made the difference. This same workout protocol showed the ability to improve cardiorespiratory and cardiovascular parameters even in well-trained athletes.[83] It also decreased the delayed-onset muscle soreness, the feeling of soreness lasting 24 to 48 hours after the workout, in the ICE group.[85] Similar protocols showed the same promising results in body composition change and cardiovascular benefits.[86,87]

Safety of Interval Exercise

HIIT, as well as intense weight training, can be used effectively and safely when combined with the appropriate use of HR monitoring, perceived exertion rate (PER), and the use of intervals: periods of exertion followed by rest. Studies show this type of activity is manageable in several illness models, including chronic obstructive pulmonary disease,[88,89] post coronary artery bypass patients,[90] congestive heart failure,[91] and heart transplantation patients.[92] This type of anaerobic stimulus more realistically mimics real-world challenge and allows for self-paced exercise that is safe, tolerable, and more beneficial for many heart and lung patients.[88-96] Cardiac patients also may have less risk with this type of activity, since it has more favorable affects on ST-segment changes and heart rate variability (HRV).[94-96]

Monitoring HR is useful for any health care provider prescribing exercise. It is important to understand that HR equations are merely estimates based on age; there is much variability. HR equations, in general, underestimate HRs in the very fit. The old HR equation of 220 – age is an inferior HR equation that underestimates HR in the old and overestimates in the young.[97] Newer equations allow for better predictive value. Based on current understanding, women and men should use separate equations for predicted HR percentages. For men, the MHR equation should

be 208 – age (0.7).[97] For women this equation should be 206 – age (0.88).[98] It is also useful to know the equation for translating percent of MHR to percent of oxygen uptake (VO_2) and vice versa. That equation is %MHR = (0.64) %VO_2 + 37.

Because multiple drugs and disease states can interfere with HR, exertion ratings used alone or combined with HR are a more useful clinical tool. In exercise research, a 16-point exertion scale called the Borg scale is used. It is a cumbersome tool to use and teach in clinical practice. A simple 1 to 10, with 10 being maximum exertion and 1 being at rest is a far more useful tool clinically. It is easy to teach and implement. Traditional aerobic exercise scores between 6 and 8 on the 1 to 10 scale. HIIT will reach between 8 and 10 on the work phase and between 1 and 4 on the rest phase. In clinical practice, this is a useful aid in working with exercise intensity. Combining HR percent monitoring with PERs and heart rate recovery (HRR) allows for tight control of workout safety.

Two other useful clinical tools for health care practitioners are the "talk test" and HRR. Exertion and respiration are closely linked. The ability of a person to talk during exercise is a direct indication of whether they have crossed into the anaerobic zone.[99] For the unfit, this usually occurs around 55% of VO_2 max and for the very fit it occurs around 85% VO_2 max. This corresponds to 72% MHR and 91% MHR, respectively, leaving the average healthy exerciser right around 80% of MHR for the anaerobic threshold, at which point their ability to talk will be compromised. Correlating this "talk test" with an individual's HR allows practitioners to closely monitor exercise. HRR is a measure of how fast the heart recovers from exertion and is an indication of sympathetic and parasympathetic tone. A healthy heart should recover at least 25 beats/min or more within 1 minute after exertion. A heart that recovers 10 or less beats in 1 minute is a concern that should constitute a referral to a cardiologist.[100]

MUSCLE–BODY MESSENGERS AND INFLAMMATION

Every time the body moves, muscles release signaling molecules that communicate to the rest of the body. The endocrine properties of muscle, like fat, have been confirmed.[101-103] In the case of muscle, compounds called myokines are released in response to voluntary contraction. Myokines are cytokines, yet are derived specifically from muscle. These myokines give instructions to the body about how to function and adapt as well as hold the key to controlling chronic inflammation.

Interleukin-6: The Exercise Factor

The most important myokine related to muscle and inflammation is interleukin-6 (IL-6). When muscle contracts, IL-6 is released. IL-6 is a well-known cytokine that has long been thought to be inflammatory in nature and part of what is known as the inflammatory triad: tumor necrosis factor-α (TNF-α), IL-1, and IL-6. However, like people, IL-6 seems to behave differently depending on its origin, amount, and other cytokines around it. When released from muscle and in high concentrations without TNF-α and IL-1, IL-6 is anti-inflammatory.[104,105] IL-6 acts to reduce the amount of TNF-α and IL-1 in circulation by increasing the cytokine inhibitors, IL-1 receptor antagonist (IL-1ra), and soluble TNF receptors (sTNFR).[106-108] IL-1ra antagonizes the IL-1 receptor, decreasing IL-1 effects, whereas sTNFR binds up TNF-α before it can react at its target cells. At the same time, IL-6 triggers the release of the major anti-inflammatory cytokine, IL-10.[107,108] It appears that exercise-induced IL-6 has unique action as opposed to TNF-α mediated release of IL-6.[104] Exercise causes a huge increase in IL-6, far above TNF-α levels. This is in sharp contrast to infection or sepsis, which shows an exponential rise in both. It may be the ratio of IL-6 to TNF-α that is the real concern with regard to chronic inflammation. Epidemiologic studies on TNF-α and IL-6 genetic polymorphisms support this, showing that those with the highest TNF-α and lowest IL-6 levels have the greatest risk of diabetes.[109]

Other researchers support TNF-α as the real inflammatory culprit.[104] They speculate IL-6 levels may be a marker of whole body TNF-α levels and could be acting in direct opposition to the more inflammatory cytokines. The IL-6 effect implicates exercise as a first line defense against inflammation and may explain the "counter intuitive" findings on the benefit of resistance training in highly inflammatory diseases like rheumatoid arthritis.[110] For some time, science has been searching for a molecule that could account for the acute metabolic effects of exercise. Exercise reduces "all-cause mortality" due to its effects on the leading killers: heart disease, diabetes, and cancer.[111,112] IL-6 is beginning to be shown as protective against diseases like diabetes.[109,113-115] These same diseases have strong links to inflammation, which is now suspected as a major underlying cause. It has long been thought that exercise's impact on weight loss was the reason behind this. However, IL-6 also plays a role as a mediating factor in exercise's effects on fuel metabolism.[101-103,114,116] The broad effects IL-6 has on inflammatory cytokines, fuel metabolism, plus its ability to "talk" to the brain, liver, and adipose tissue, has some researchers thinking it is the best candidate for the elusive exercise factor.[106]

As muscle contracts, the genes controlling IL-6 production are turned on. The degree of IL-6 released from muscle is directly proportional to the amount of muscle being contracted; the more muscle used, the greater the response.[106,107,117-119] IL-6 also shows a tight relationship to muscle glycogen and exercise intensity. When muscle sugar stores begin to decrease, an intensity threshold is breached and much larger amounts are released.[120] Increasing exercise intensity, full body muscle contraction, and muscle glycogen depletion are the major exercise elements enhancing IL-6 release from muscle.[102,117,120,121] These factors together can induce an increase of plasma IL-6 that is 20- to 100-fold over resting levels.[102,121] At these levels, IL-6 begins to exert influence over the body, relaying messages about the metabolic needs of the muscle. In this way, IL-6 acts more like a hormone than a cytokine by sending communications from muscle to adipose tissue, immune cells, and the liver. These messages instruct the body to burn fat, control glucose regulation, inhibit the production of the proinflammatory cytokines, and ultimately generate a fully anti-inflammatory effect through the release of IL-10.[122] IL-10 is a potent reducer of TNF-α and IL-1 in its own right.[107]

From the previous scenario, it should be apparent that the ability to harness IL-6 through exercise could have a significant effect not only on inflammation, but also on whole body fuel usage and tissue repair. This process is far different than the usual chronic inflammatory scenario. A situation of chronic inflammation is one where TNF-α is elevated along with IL-6 and IL-1. Exercise-induced, muscle-derived IL-6 shifts the balance, causing a reduction in TNF-α and IL-1 with a simultaneous increase in IL-10.

In addition to its more direct effect, exercise-induced IL-6 has other secondary effects that account for increased benefits. 11β-Hydroxysteroid dehydrogenase type 1 (HSD1) is an enzyme that should be on the radar of physicians. It is responsible for the conversion of cortisone into active cortisol. This cortisol/cortisone ratio is important in determining the possible detrimental effects

of cortisol. This enzyme is present in visceral adipose and is overly active in the overweight and obese.[123] This is an important revelation, since it points to visceral adipose tissue as a new site of cortisol production. TNF-α and IL-1β have both been shown to upregulate HSD1 and contribute to total glucocorticoid production.[123] IL-6 is a potent inhibitor of both TNF-α and IL-1β, and the largest amounts are released through exercise. Intense exercise potentiates these effects by increasing sympathetic stimulation of α-2 receptors as well as adrenocorticotropic hormone; all of these have independent effects in suppressing HSD1 activity. The ability to blunt HSD1 is beneficial in controlling obesity and diabetes, and intense exercise may be the best way to effect these changes.

In addition to the cytokine effects, exercise-induced IL-6 crosses over into hormonal action and allows the muscle to "talk to" the adipose tissue and the liver.[101] Its major action at these sites is to release energy substrate to fuel continued movement. IL-6 is a potent stimulator of adipose tissue fatty acid oxidation[104] and is a major factor in liver glycogenolysis.[101] Although the mechanism for this action has not yet been fully elucidated, studies have confirmed that IL-6 has direct effects on the expression of adenosine monophosphate kinase[117,118] and hormone sensitive lipase,[113] two chief fuel regulating enzymes in human tissue.

Finally, IL-6 has the ability to cross the blood–brain barrier, having direct effects on the brain. The brain produces IL-6 in response to exercise as well. This sparks curiosity as to what brain IL-6 is doing. Animal studies showed that IL-6 had a direct and important effect on the brain, thus playing a role in appetite regulation, fuel regulation, and body composition.[101]

Interleukin-15: The Arnold Cytokine

Along with IL-6, IL-15 is another myokine that works to reduce inflammation in less direct ways. This cytokine works by interacting with transcriptions factors, such as peroxisome proliferator activated receptor-δ, decreasing adipose tissue size while at the same time increasing muscle contractile elements and size.[124-128] The end result will be less adipocytokine release (inflammation) due to a decreased fat mass, and a higher potential secretion of myokines (anti-inflammation) due to a greater contractile potential.

IL-15 is emerging as a potent antiobesity weapon and may explain why resistance exercise, which does not typically burn as many calories as aerobic exercise, dramatically impacts body composition. We like to refer to this myokine as the Arnold cytokine after the famous bodybuilder and actor Arnold Schwarzenegger. Bodybuilders are able to develop extremely lean and muscular physiques while focusing almost all their attention on high intensity resistance exercise as opposed to aerobic exercise.

Research showed that IL-15 release is twofold higher in type-2 dominated muscle tissue and that resistance exercise doubles IL-15 concentrations 24 hours after exercise.[124,125] This shows a novel mechanism of resistance exercise against the accumulation of fat. The effects of IL-15 are not the same in type-1 muscle fibers, which are dominate in aerobic activities. IL-15 has profound effects on reducing adipose tissue size while at the same time acting to increase muscle tissue. These effects are desirable, because muscle mass is frequently lost along with fat in aerobic centered exercise programs.

Interleukin-8: Angiogenesis

IL-8 is another myokine that may help the body heal through its ability to build greater blood supply. It is produced whenever the muscle encounters low oxygen supply, such as when it undergoes intense anaerobic exercise. It appears IL-8 is a potent angiogenic factor that signals the body to begin to build new blood vessels to increase blood supply. The muscle release of IL-8 is intuitive and self-serving for the muscle, allowing the tissue to meet the demands of activity the next time around. It appears that IL-8, like IL-6, is associated with intensity of exercise. It is released in highest concentration as a response to exhaustive aerobic exercise and during eccentric contraction. The myokine appears to act locally, inducing the angiogenic effects in the muscle tissue only. This is in contrast to IL-6 and IL-15, which, despite being cytokines, cross over into hormone-like action when induced through exercise.[129]

Lactate

Lactate has been correlated with several positive benefits to exercise. It is now believed that lactate is directly related to some of these beneficial changes through hormone-like action. As exercise intensity escalates, there is a large surge in catecholamine production. This occurs to supply the body with much needed blood sugar to fuel intense exercise. As the exercise intensity increases, aerobic physiology becomes "maxed out," forcing the body to become more anaerobic. This switch, believed in the past to be due to an oxygen deficit, is currently understood to indicate mitochondrial shuttle saturation. When this occurs, pyruvate and hydrogen ions begin to accumulate in the cytosol. It is the accumulation of hydrogen ions that lowers the pH of the cell, causing fatigue and the familiar muscle burn of intense exercise. In this situation, lactate is quickly formed. Lactate can then be recycled back to glucose via gluconeogenesis, be burned directly by conversion back to pyruvate and entry into the Krebs cycle, and/or engage cellular machinery as a signaling molecule.

The major signal sent by lactate during exercise seems to be an "adaptation signal." Analysis of this action shows that lactate has two major functions: first, it increases cellular events, leading to mitochondrial generation,[130,131] and second, it stimulates the release of growth promoting hormones, including HGH and testosterone.[132-134]

The major action on cellular signaling seems to be the upregulation of MCT-1.[130] MCT-1 is an embedded protein in the mitochondrial membrane that speeds the formation of pyruvate from lactate, thus making existing mitochondria more efficient. In addition, research by Hashimoto et al[131] in 2007 elucidated a complex mechanism whereby lactate interacts directly with key genes involved in mitochondrial biogenesis. Taken together, this opens a whole new understanding for improving metabolic efficiency. By harnessing the power of lactate, mitochondrial levels can be increased and enhanced, resulting in many beneficial effects on total physiology.

The idea of lactate as a hormone is a novel concept. However, it has been made clear through several studies over the last few years that lactate is a key signaling molecule in exercise metabolism. Interestingly, a lactate receptor called GPR81 was recently isolated in rats, confirming it does act like a hormone.[135] Other studies have shown lactate can directly stimulate the release of testosterone, progesterone, and HGH.[132,133,136-138] This lends further credibility to lactate's role in helping the body adapt and grow.

TESTOSTERONE AND HUMAN GROWTH HORMONE

Testosterone and HGH, in particular, are key players in human metabolism, especially as they pertain to physique development, combating obesity, and antiaging effects. Testosterone and

HGH, in addition to other effects, increase lean muscle tissue and decrease fat mass. Both of these anabolic hormones are more pronounced with anaerobic exercise.

EXERCISE APPROACHES TO INFLAMMATION

IL-6's release from muscle cells is not a nervous system phenomenon and is not based on muscle injury. It seems the impetus for IL-6 release is mechanical.[103,121] In other words, just the act of movement is all that is required. However, there are ways to amplify IL-6 production during exercise. The science of exercise metabolism now goes far beyond simple calories. The ability to harness the far-ranging hormonal and cytokine effects of exercise can be accomplished through use of short duration high intensity exercise techniques used in athletic populations for decades. Although the term "high intensity" has the tendency to cause reservation, these tools and techniques can be adapted for use in even the least fit and most populations with inflammation.[110,111,139]

Before discussing the techniques in this approach to exercise, it is important to define why short intense exercise may be more useful than traditional approaches. The damage associated with chronic inflammation is compounded by a lack of offsetting growth factors. The body produces these growth factors in response to intense exercise. Testosterone and especially growth hormone are known to be factors linked closely with intensity. The word intense as used here means exercise that is glycogen depleting, i.e., it significantly reduces the body's muscle and liver sugar stores. Only two types of exercise are likely to produce these effects, long duration exercise lasting hours or short intense sprint type exercise. There are obvious constraints to prescribing hour long exercise sessions, since lack of time is the number one reason cited for lack of exercise participation, making short intense exercise more realistic. In addition, the overall hormonal response to long duration exercise is counterproductive, since it raises cortisol levels above the body's ability to compensate with growth promoters.[46-53]

This type of exercise also makes sense because it creates a hormonal environment that produces sustained fat burning as well as muscle growth.[54,66,140] The amount of glycogen reduction is directly correlated with IL-6 release and high intensity exercise is shown to increase IL-6 and catecholamines together.[103,107,120,121] Catecholamines have their own independent effect in lowering TNF-α and IL-1, synergistically enhancing IL-6. Combining these known effects with techniques that can deliver the same benefit in less time presents the opportunity to supply these anti-inflammatory effects in short time periods.[107,122,141]

Holistic Fitness Prescription

Based on the research reviewed in this chapter of the new understandings emerging from exercise research, it seems a cross-training approach in line with our historic movement patterns would provide the most benefit. This approach would include walking, aerobic zone exercise, and resistance training, as well as cardiovascular interval training. However, realizing exercise prescription needs to be feasible and time consciousness necessitates combining elements to generate the most health benefit.

Putting this information in the historical context, it would appear that daily walking should be done as much as feasible. Walking should be viewed as a necessity rather than exercise. Based on historical information, walking constituted the predominant activity of our ancestors. Walking not only burns calories, but also has restorative and relaxing effects. Because walking and eating are generally incompatible, it may be a suitable replacement for eating behavior. Walking may best be done in the evening and for hormonal benefit; walking in a natural setting may be more beneficial than walking in more urban settings.[142] Studies have shown positive effects on lowering cortisol.[142]

In addition to walking, aerobic zone training should be instituted as well. Based on most data, an aerobic program lasting between 20 and 60 minutes 3 to 5 days/week seems optimal. Based on new information, aerobic exercise may be best for weight maintenance and not the most optimal for attaining weight loss. Given the new data on HIIT, the time spent doing aerobic exercise may be able to be cut in half. A HIIT program done 3 times/week for 20 to 40 minutes could save considerable time[69] and provide the same cardiovascular benefit and perhaps better weight loss results without the compensatory food behaviors.[55-61]

Recommendations capitalizing on the concept of nonexercise associated thermogenesis (NEAT)[143] and burst training[144,145] may have special applicability in today's time-starved world. NEAT involves accumulating as much nonexercise related activity as possible and includes everything from washing the dishes to fidgeting with a pencil, to nervously bouncing a leg up and down and even nonsitting time. Burst training is a concept popularized by Mark Smith, PhD, and involves accumulating several 1-minute anaerobic bouts of activity throughout the day. Several interesting studies showed this approach was able to generate clinically meaningful weight loss results with only minutes of exercise per day.[144-146] Instituting behavioral changes that involve parking further away, doing a burst of activity by running up the steps, standing rather than sitting, and even fidgeting when standing or sitting still can all make a significant impact on total energy expenditure.[143]

Weight training programs should also be a center point of health, fitness, and fat loss.[147] Resistance exercise excels at maintaining muscle mass and helps attenuate rebound weight gain.[148] Three full body workouts per week, using moderately heavy weights in the 8 to 12 repetition range for 3 to 5 sets is optimal. Again, since time is an increasingly limiting factor, integrating resistance training with interval training into one workout 3 to 5 times/week for 30 to 60 minutes can save considerable time yet still yield significant caloric expenditure and fat loss.

Rest-Based Training Method for Exercise Prescription

Rest and movement are often seen as opposites, but they are actually complementary and dependent on each other. Exercisers told to run as fast as possible for 10 minutes will necessarily regulate intensity to complete the task. If they were instead told to run as fast as possible for 10 seconds, the intensity could be dramatically elevated. True high intensity exercise is impossible to achieve without rest. Quality rest leads to quality work and vice versa.

HIIT and intense weight lifting have always coupled work with rest. One issue with these workouts is the rigid structure. The work/rest ratios "force" individuals of varying fitness levels to work at mandated levels. This works to lower intensity, inducing the same pacing effect seen in traditional aerobic exercise. These types of workouts are often too intense for many and can create psychological resistance to participating.

Rest-based training (RBT) uses rest, autonomy, and time manipulation to optimize intensity for all fitness levels. It combines the latest in exercise science and motivational psychology. RBT enjoys the same physiologic benefits of intense interval exercise and weight training but with key psychological benefits.

RBT differs in the application of rest. Although interval training and weight training have clearly defined work and rest ratios, RBT leaves the exerciser in charge of the duration of rest. The

language employed in this type of training is "push until you can't, rest until you can." This shift in paradigm acts as reverse psychology for exercisers.

Motivational psychology of exercise is an important consideration regarding exercise consistency, frequency, and intensity. The primary goal and purpose of interval training is to maximize work effort across all work bouts and employ the shortest recovery time possible to maximize the training stimulus. Contrary to popular belief, research has shown that exercisers who have autonomy over their workout parameters will often work harder and are able to self-regulate to an optimal work/rest ratio for their physiology.[148-150]

There are four key attributes in our RBT system. All are geared towards maximizing work effort in a safe and scalable way. The key tenets of rest-based exercise are represented by the acronym REST.

Rest-Based

Pushing to the point of rest is actually the goal of a rest-based workout. By putting the focus on rest, as opposed to work, RBT not only automatically increases the quality of work, but also makes exercise psychologically easier.[148-151] When exercisers know they have permission to rest, they may voluntarily work harder without even being consciously aware they are doing so.

Interestingly, animal research showed that intermittent exercise is inherent and may be an evolutionary adaptation to maximize distances covered per unit time.[150] Animals naturally engage in sporadic work/rest ratios during movement and self regulate exercise to optimize both performance and recovery. Research showed that humans have the same capability.[148]

Extrinsic Focus

A major inhibitor of intensity is exercisers' focus on intrinsic sensations such as breathlessness, burning, and other uncomfortable feelings.[149,152] RBT uses strategies that focus participants away from these intrinsic sensations to more extrinsic factors. Workout parameters change quickly, monotony is minimized, circuits are utilized, exercise timing is limited, and different movement strategies are incorporated in the same workout. All of this is designed almost as a distraction technique so the exerciser focuses more on what they are doing versus what they are feeling. This helps them work harder and therefore rest more often.

Self-Determined

In psychology research, self-determination theory posits that when people are given control and choice over their options, internal motivation automatically increases.[153-155] With RBT, there is structure in the workout, but the exerciser is left in complete control over how hard to work, when to rest, for how long, and even has flexibility over exercise choice and modifications. These factors serve to not only increase the quality of work within a session,[148] but can also improve exercise adherence from session to session.[148,149,152-155]

Time Conscious

Given that time and intensity are so closely linked, harder workouts by necessity must be shorter. RBT workouts can be as short as a 1-minute burst repeated multiple times throughout the day, to as long as 40 minutes of continuous exercise employing start and stop working and resting. Workouts lasting over 40 minutes suffer in intensity and may have negative hormonal consequences.[58,59,69]

Work/rest ratios employed by traditional interval and weight lifting workouts work for some but can be imperfect for most. By focusing on rest in a workout and allowing exercisers control over when they rest and for how long, optimal intensity for results can be achieved in a safe, scalable way. A 96-year-old grandfather would be able to use the same workout approach to deliver optimal intensity for him, whereas a 24-year-old elite athlete could use the concept to deliver an optimal intensity as well. Rest-based exercise can be seen as a new functional model for fitness and fat loss.

EXERCISE AND THE HEART

Aerobic zone exercise is a well-known preventive and treatment strategy for cardiovascular disease. Virtually all health care providers are aware of the aerobic exercise prescription advocated by most policymaking organizations as "20 to 60 minutes of aerobic exercise done at an intensity of 65 to 80% of MHR on all or most days."[156] Given that these recommendations are well established and universally accepted, we will focus our attention here on new research related to the heart.

Since the publication of the book *Aerobics* by Kenneth Cooper in 1968, participation in activities such as jogging, biking, swimming, marathons, and triathlon training has steadily risen. Newer research suggests, however, that this approach can be taken too far and exercise for health, fitness, and fat loss should not be so one-dimensional. Dr. Cooper himself has conceded "In that book I said, 'The more exercise, the better.' But by 1982, after too many telephone calls from distraught widows whose 55-year-old, overweight smoker husbands had died jogging, I realized I had made a mistake. … Exercise wasn't a panacea that could fix everything, it had risks.… There may be a point of diminishing returns."[157]

The risks of excessive aerobic exercise are now being better understood. Ultra-endurance exercise, such as marathon running and triathlons, can have a negative impact on heart function. Intense long duration aerobic activity dramatically elevates oxidative stress in the heart, alters left and right ventricle function, and causes damage in otherwise normal hearts.[158-160] This is not to say aerobic exercise is dangerous, but rather to highlight the potential downside of an aerobically dominated exercise prescription.

Obesity may actually be a better target for exercise therapy because it is so closely related to heart disease. Any exercise approach that helps lower body fat can be viewed as a heart healthy plan. Because so many view exercise as a time-consuming chore and lack of time is the number one reason cited for lack of participation in exercise, interval training exercise prescriptions may be better suited to heart protection. More research needs to be done at this point, but there is already promising information that intense interval training has all of the upside of aerobic exercise, while being well tolerated**,** safe, and more feasible in terms of time.

Interval Training the Heart and Vascular System

The theory behind interval training is that the heart, like all muscles, needs to be challenged to repair and grow stronger. Theoretically, interval training allows the advantage of a harder challenge with less risk because each high intensity bout is followed by recovery. If done correctly, the heart is forced to alternate between sympathetic stimulation and parasympathetic recovery. This, it is argued, is a more functional way to exercise because it trains HRR and heart stimulation. Because many cardiac events come from sudden unexpected anaerobic challenges, like shoveling the first winter snow, running through an airport to catch a plane, or walking up a large flight of steps, HIIT is believed to help the body prepare for these challenges by teaching the heart to work and recover quickly.

HRV and spontaneous cardiac baroreflex provide functional measures of cardiac parasympathetic activity. A study in April 2005 showed the effect of interval training on both.[161] Eleven healthy elderly men, mean age 74 years, underwent an intensive 14-week interval training program involving nine 1-minute bouts of exercise at 85% MHR followed by 4 minutes of recovery at 65% MHR. Aerobic capacity increased 18.6%, whereas HRV showed a significant parasympathetic shift at night from pre- to post-training. The cardiac baroreflex response also improved, with 10 of the 11 participants showing a favorable response.

Benefits of HIIT may be good for peripheral vascular disease as well as cardiovascular disease. A 2006 study reported an observational study on the effect of HIIT on intermittent claudication.[162] A total of 47 patients were included in the study. Patients were asked to walk on a treadmill to maximal claudication pain six times in each exercise session with 3 minutes of rest in between. Once a patient could walk continuously for 6 minutes without reaching maximal pain, the speed and/or grade was increased. A rehabilitation score was calculated as the product of speed and grade achieved by the participants. Results showed that HIIT led to clinical improvement in symptoms and a higher tolerable workload by patients. No adverse effects were seen from the treatment, suggesting those with peripheral arterial disease could both tolerate and benefit from HIIT.

In 2007, Wisløff et al[163] shed some light on the cardiovascular effects of HIIT versus traditional aerobic training for heart failure patients. Twenty-seven patients with stable postinfarction heart failure were randomized to either aerobic exercise (70% MHR) or HIIT (95% MHR for 4 minutes separated by 3 minutes at 50% to 70% MHR) 3 times/week for 12 weeks or to a control group. The control group was told to follow the exercise advice of their family doctor and met for 47 minutes of walking at 70% MHR every third week. All groups did exercise on a treadmill. The major finding was that HIIT was superior to traditional aerobic training with regard to reversal of left ventricular (LV) remodeling, aerobic capacity, endothelial function, and quality of life. With respect to LV remodeling, in the HIIT group, the LV diastolic and systolic diameters decreased by 12% and 15%, and estimated LV end-diastolic and end-systolic volumes dropped by 18% and 25%, respectively. Prohormone brain natriuretic peptide, a marker of hypertrophy and severity of heart failure, declined by 40% in the HIIT group. There was no change in the traditional aerobic group or control group in LV remodeling, pointing to a rather profound effect of HIIT on traditional aerobic exercise in this patient population.

As mentioned, HIIT has been shown to be safe and well tolerated in chronic obstructive pulmonary disease,[88,89] postbypass patients,[91] congestive heart failure,[90] and even heart transplantation patients.[92] As discussed, HIIT may realistically mimic real-world challenges. It can also be tailored into a self-paced format that is safe, tolerable, and beneficial for many cardiovascular conditions.[93-96] It was shown in one study to have more favorable effects on ST-segment changes than traditional aerobic exercise, in addition to the positive effects on HRV.[94-96,98]

Obviously physicians prescribing exercise for high-risk patients will not want to completely abandon traditional aerobic exercise in favor of HIIT. Traditional aerobic exercise is well established to both treat and prevent cardiovascular diseases. More studies need to be done on HIIT, but it appears it may have some unique cardiovascular benefits. There are some considerations when prescribing this form of exercise. Work/rest ratios should be larger for the more fit and smaller for the less fit or more frail. A beginning exercise protocol for a younger fit person wanting to optimize cardiac prevention would be a work/rest ratio of 1:2. More frail and less fit clients will want to start with a work/rest ratio of 1:4 or greater. The RBT approach highlighted previously may provide increased benefit and safety when using intervals.

EXERCISE AND BONE

When prescribing exercise for bone, there are several important considerations: the mechanostat theory, the concept of osteogenic sheer forces, and most importantly, knowing that bone density does not necessarily equal bone strength. A strong bone is both dense and flexible, whereas a weak bone has only one or none of those qualities.[164]

The mechanostat theory states that bone has set points of minimum effective strain (MES) that determine whether or not bone will be gained or lost.[165,166] If forces on bone increase more than what the bone is accustomed to (i.e., relative MES), mineral flux into bone increases. This, along with compensatory structural changes, helps bone become competent enough to deal with increased functional demand. Likewise, if demands on bone decrease and fall below the MES threshold, bone metabolism changes result in weaker bone.[167] The latter scenario often prevails in age and illness and can happen very quickly. During periods of immobilization, bone mineral density can decline as fast as 1% per month.[168,169]

To understand the concept of osteogenic sheer forces, one must have some idea of the bone's anatomy. Cortical bone contains lacunae (hollowed out areas) that are connected via canals (canaliculi). These lacunae house osteocytes that extend dendritic arms through the canaliculi to communicate with other osteocytes. Osteocytes act as mechanoreceptors. The osteocyte and its dendritic arms are bathed in fluid. The movement of this fluid is believed to be "sensed" by the osteocytes. The degree of intensity of this fluid movement dictates the degree of bone building stimulation. Research hints that exercise that creates large "sheer forces" such as jumping creates the most potent stimuli for bone growth. Another key factor in this physiology is that small jostling forces have a much weaker effect, and continuous exercise may work against bone building by causing desensitization of osteocytes. Optimal bone building exercise therefore is sporadic in nature, alternating work and rest and creates large strain and sheer forces. Multidirectional jumps and hops seem to be most ideal.

Measuring bone density alone does not provide an adequate measure of bone strength.[164] To determine the full impact of exercise, all bone parameters should be assessed. To properly ascertain bone strength, cortical thickness and bone diameter are equally important compared with bone mass. Cortical bone, the outer portion of bone, is responsible for 80% of bone strength. Thicker bones are also stronger bones. By measuring density, cortical bone, and thickness, we get a much more accurate picture of how much force a bone can handle. Effective exercise should address all these areas. In addition, bone-building exercise should be aimed at developing functional parameters that prevent a fall in the first place.[170,171] This means exercise modalities that build strength, flexibility, balance, and reaction speed should not be ignored.

EXERCISE AND CANCER

Yoga therapy has been shown to predict survivability in breast cancer,[172] is correlated with better outcomes in cancers of the head and neck,[173] and allays anxiety and stress-related dysfunction in cancer treatment.[174,175] The research on yoga and its use in cancer is gaining ground. A report by Brauer et al[176] in 2010 looked at the leading cancer treatment hospitals in America. This study showed 56% of these centers incorporated yoga into their clinic offerings.

The wasting of cancer, cachexia, is a difficult condition to treat, with few therapeutic options. Resistance training has several unique mechanisms that seem to address several of the underlying mechanisms of cachexia.[177] Resistance exercise is able to increase phosphorylation of mammalian target of rapamycin (mTOR) and p70S6k.[178] This suggests it has the potential to block a major contributor to decreased muscle synthesis. Resistance training is also a powerful modulator of adenosine triphosphate-dependent ubiquitin-proteosome system (UPS) activity by way of inflammatory cytokine modulation. Two review articles in 2007 by Pajak et al[179] and Al Majid et al[180] showed several complicated mechanisms of how resistance exercise works. Resistance exercise can release IL-6, which is anti-inflammatory when released by muscle,[82] and IL-15, which is strongly anabolic. Muscle-derived IL-6 suppresses TNF-α and IL-1. This action strongly decreases the overactivity of adenosine triphosphate-dependent UPS, which may be the most important component of cancer cachexia. IL-15 also will increase the type II muscle fibers that seem to be selectively lost in cachexia.

EXERCISE FOR THE BRAIN AND MOOD

Exercise increases cerebral blood flow and metabolism and therefore impacts both mood and cognitive function. Exercise has been shown to have many positive benefits on mood, especially in the realm of depression, anxiety, and self esteem.[181] In one depression study, 50 adults classified with depressed mood on the Profile of Mood States-Short Form Depression Scale (POMS) were studied over 10 weeks.[182] The treatment consisted of moderate intensity aerobic exercise for 30 minutes three times per week. At the end of the study, 62% of the exercise group were classified as normal on POMS compared with 29% in the control group. Another study in the elderly showed comparable results.[183] Several mood parameters were assessed, including both depression and anxiety. The study group had decreased scores for depression and anxiety and showed significant improvement in quality of life scores.

Two other studies on depression showed exercise as a potential primary therapy in major depression and among patients refractory to drug therapy. A study published in 2001 showed a small group of subjects with major depression who underwent a daily 30-minute walking program had clinically relevant and statistically significant benefit from exercise in as little as 12 days.[184] The program was a moderate intensity interval-walking program alternating from "somewhat hard" to half that pace on the rest phase. Even subjects refractive to drug therapy were able to improve with the exercise program. Considering the well-known response delay of 2 to 4 weeks with the use of medications, this study showed aerobic exercise as a more immediate fix and a smart integrative approach with drug treatment.

Direct comparisons of exercise versus drug therapy (sertraline) for major depression showed exercise as a powerful mood enhancer.[185] Subjects performed aerobic exercise on a treadmill 3 times per week and were followed over a 12-month period with respect to Zoloft therapy, exercise and Zoloft therapy, and exercise alone. The exercise alone group had significantly better outcomes in terms of treatment effect, remission, and relapse than either the Zoloft group or the Zoloft group plus exercise.

EXERCISE AND ANXIETY

Exercise has favorable effects on anxiety. Past studies have shown exercise to be an anxiolytic in caffeine and carbon dioxide induced symptoms,[186,187] but these compounds did not result in panic. One study showed that direct treatment of panic disorder patients with aerobic exercise led to significant improvement compared with placebo.[188] The study was over a 10-week period, and maximum effect was seen towards the end of the study. This points to exercise as both a preventative and alternative treatment strategy for anxiety. The acute effects of exercise may even be able to allay panic attacks. A recent study used exercise as a treatment against induced panic attacks.[189] Cholecystokinin tertapeptide (CCK-4) is a reliable inducer of panic attacks in humans and mimics the mechanisms associated with anxiety-induced panic attacks. Fifteen subjects were studied in a crossover design. Exercise for 30 minutes at 70% of maximum oxygen consumption was compared against no exercise. The following day, subjects received a bolus of CCK-4 and were monitored for signs and symptoms of panic attack. Previous exercise the day before produced half as many panic attacks, 6 compared with 12. This appears to indicate exercise as a modifier of anxiety-induced panic attacks.

EXERCISE AND MEMORY

Exercise also impacts memory and has shown benefit in multiple brain parameters.[190] Even weight lifting can improve brain function in the elderly.[191] Exercise is known to increase neurotransmission as well as myelin synthesis. Taken together, this can both increase the speed and quality of mental activity. Studies have shown exercise positively impacts attention deficit disorder/attention deficit hyperactivity disorder, dementia, Alzheimer's, and other mental disorders.[192-195] Recent studies also showed that exercise has the potential to create new neurons.[194,195]

SUMMARY

This chapter illustrated the vast potential of exercise to both prevent and treat multiple medical issues from obesity to mental and emotional dysfunction. There are many aspects of exercise and health that were not covered or were only discussed briefly. However, the key concepts covered should allow smart manipulation of exercise parameters to fit many conditions. It is our hope that understanding the new science of exercise, as well as the historical construct in which movement evolved, will allow health practitioners to move beyond one-dimensional exercise models focused solely on aerobic exercise to a more holistic and functional model of prescriptive movement.

INTRODUCTION

Humans, unlike chimpanzees, have the ability to survive on water for extended periods of time.[1] The primary adaptation is the ability to use ketones from fat metabolism as an alternate fuel for the central nervous system.[2] The beauty of this adaptation is that during fasting the body prioritizes fat catabolism, the most concentrated caloric energy resource (9 vs 4 kcal for carbohydrates and protein), and thus safeguards catabolism of essential structures (nerves, muscles, organs, etc.) until stored adipose tissue is severely depleted—after fasting several weeks to months, depending on fat stores as well as metabolic, stress, and activity level. However, once this threshold is crossed in unattended fasting, starvation ensues (the body uses essential tissue for fuel, relying on protein as a major fuel source), resulting in death due to organ failure.[3]

Therapeutic fasting is voluntary, supervised abstinence from all food and drink except water for a specific time. The health promoting benefits are due to the marshalling of our metabolic potential as cellular systems manage internal resources more efficiently. The body thus can restore structure and function in a way analogous to rebooting a computer that has stopped working properly. Unlike a machine, however, the body can adapt dynamically to its internal environment, allowing the body to do what it does best, heal itself.

HISTORY

Throughout history, people of various cultures and religions have recognized the value of fasting. Numerous references appear in the Bible, Koran, pagan writings, and writings of the ancient Greeks.[4-6] One of the earliest doctors to use therapeutic fasting in the United States was Isaac Jennings (1788 to 1874). In 1822, Jennings discarded the use of drugs and, through the influence of Presbyterian preacher Sylvester Graham (1794 to 1851), began advocating fasting and other aspects of hygienic treatment (vegetarian diet, pure water, sunshine, clean air, exercise, emotional poise, and rest). This treatment later came to be known as "natural hygiene."[5-9] Other doctors who followed in the hygienic tradition were James C. Jackson (1811 to 1895), Russell T. Trall (1812 to 1877), William A. Alcott (1798 to 1859), Mary Grove Nichols (1810 to 1884), Thomas L. Nichols (1815 to 1901), Edward H. Dewey (1837 to 1904), George H. Taylor (1821 to 1896), Harriet Austin (1826 to 1891), Charles E. Page (1840 to 1925), Emmett Densmore (1837 to 1911), Helen Densmore (? to 1904), Susanna W. Dodds (1830 to 1915), Felix Oswald (1845 to 1906), Robert Walter (1841 to 1921), John H. Tilden (1851 to 1940), and George S. Weger (1874 to 1935). Most of these physicians graduated as medical doctors (MDs) from eclectic medical schools and published various works on lifestyle, diet, and fasting.[7-14]

The hygienic lineage continued into the mid-1900s, mainly due to Herbert M. Shelton, DC, ND (1895 to 1985), who developed a stricter protocol for fasting (water only; no enemas, exercise, or treatments; and complete rest). Shelton began his study of fasting in 1911 by reading the popular writers of his day: Sinclair, Carrington, Hazzard, Haskell, Purinton, Tilden, and MacFadden. He studied under the fasting authorities of his time at MacFadden's College (Chicago, Ill.), Crane's Sanatorium (Elmhurst, Ill.), and Crandall's Health School (York, Penn.).[7,12] (Among the earliest fasting institutions of this time were Lindlahr's Nature Cure Sanatoriums, including the Jungborn—the last operated by Benedict Lust, the

Data from Elkeles RS, Tavill AS. Biochemical aspects of human disease. Boston: Blackwell Scientific, 1983.

founder of naturopathy in the United States, the MacFadden's Healthatorium, and the Tilden's Health School.)[8] In 1928, he founded a fasting institution and health school that provided services for more than 40 years.[7]

In 1949, Dr, Shelton along with William Esser, ND, DC; Christopher Gian-Cursio, ND, DC; and Gerald Benesh, ND, DC, formed the American Natural Hygiene Society, now called the National Health Association,[7,14] a lay organization dedicated to preserving the tenets of hygiene. In 1978, a professional branch was formed (International Association of Hygienic Physicians [IAHP]) to study and promote therapeutic fasting. Today, the IAHP organizes clinical training and examination, leading to certification in therapeutic fasting.[15]

PHYSIOLOGY

It has been suggested that humans, like other species, have evolved special biochemical pathways to subsist for long periods without food during periods of food scarcity (climate, injury, illness).[16] While fasting, the body primarily uses fat stores from adipose tissue for energy while recycling nonessential tissue for maintenance of pivotal systems. This streamlining utilizes nonessential protein sources, including digestive and glycolytic enzymes, muscle contractile fibers, and other connective tissue. Research has determined that an average 70-kg man has the fat stores to maintain basic caloric requirements for 2 to 3 months of fasting[17-21] (Tables 37-1 and 37-2). However, as this threshold approaches, the body can no longer effectively or efficiently mobilize fat stores for fuel, and significant protein catabolism again becomes necessary for energy production.[17]

During feeding, the conversion of fatty acids to acetyl coenzyme-A (CoA) is regulated by the availability of L-glycerol 3-phosphate (derived from glucose through the glycolytic pathway). As the concentration of acetyl CoA rises, it is resynthesized into triglycerides, with L-glycerol 3-phosphate serving as the accepter to which three acyl CoA groups are attached (through esterification). Conversely, during fasting, there is inadequate glucose to provide the needed glycerol for triglyceride synthesis, resulting in acetyl CoA levels in excess of the oxidative capacity of the Krebs cycle. The excess is then shunted into the synthesis of ketone bodies.[22]

Research using respiratory quotient and urinary nitrogen studies has repeatedly shown that triglycerides are the major fuel during fasting.[17-23] Inadequate blood glucose in fasting prompts hydrolysis (lipolysis) of triglycerides within adipocytes, allowing fatty acids and glycerol to leave the cell. The fatty acids are transported in a physical complex with albumin to the liver, muscle, and other tissues. Fatty acid oxidation results in large quantities of ketones secreted into the blood stream, usually noted on urinalysis by day three.[24] These ketone bodies (acetoacetic acid, acetone, and β-hydroxybutyric acid) are utilized by the heart and, in fasting, by the brain for energy production.[2] Because the ketone bodies are acids, their entry into the plasma results in a rise in hydrogen ions. This change is buffered by the conversion of bicarbonate into carbonic acid and then to carbon dioxide, which is exhaled. In extended fasts, the buffering capacity is surpassed and the plasma pH decreases, leading to mild metabolic acidosis with a compensatory increase in respiratory rate with noted electrolyte imbalance.[22]

The initial physiologic response to fasting is the liver's increased release of glucose to maintain adequate blood levels as undigested calories are exhausted in 4 to 8 hours. After only 12 hours, the liver's glycogen stores become exhausted, and blood glucose is maintained by gluconeogenesis from triglyceride glycerol in fat reserves as well as from glucogenic amino acids and primarily from lactate (Cori) and alanine cycle from muscles.[25,26] Interestingly, muscles contain more glycogen than the liver, but lack the enzyme required to convert glycogen to glucose (D-glucose-6-phosphatase). Through the Cori cycle, stored energy is shuttled as lactate to the liver and then used by body systems as glucose, where as in the feeding state, it would commonly be shuttled back to the muscles[19] (Figure 37-1). As the fast proceeds, the kidneys become

TABLE 37-2 **Utilization of Energy Reserves**

ENERGY SOURCE	RESERVE*
Glucose	1 h
Digestion	4-8 h
Glycogen	12 h
Amino acids	48 h
Protein	3 wks (if protein were the only fuel used for gluconeogenesis) 24 wks (obligatory loss only)
Triglycerides	8 wks

*These estimates are based on 100% utilization of each fuel.

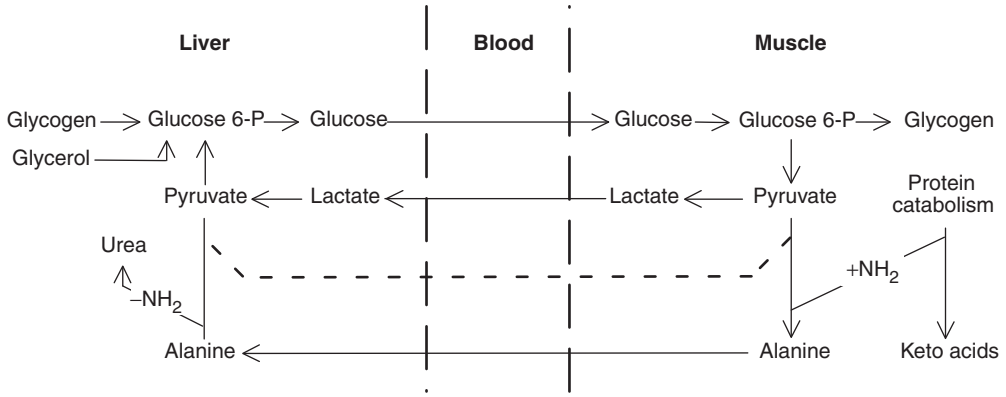

FIGURE 37-1 Mechanisms of glucose production during fasting.

progressively more important in the maintenance of blood glucose levels, and eventually, the renal cortex synthesizes more glucose from amino acids than does the liver.[16] Note that glucose is also recycled by the breakdown of blood cells in the liver.[19-21]

Under normal feeding conditions, the energy requirement of the mature brain is met almost entirely by glucose. Because the glycogen content of the brain is very low (0.1%), there is essentially no brain glucose reserve. Although the brain converts to oxidation of β-hydroxybutyrate after 4 to 7 days, there is still an obligatory need for approximately 80 g/day of glucose for the brain, red cells, muscles, and other tissues (400 to 600 kcal/day of glucose).[24,27] Approximately 16 g of glucose is synthesized from triglyceride glycerol, with the rest of the glucose requirement (and the other metabolic processes requiring amino acids, such as enzyme turnover) being met by the catabolism of 18 to 24 g/day of protein.

All amino acids are glucogenic (with the exception of leucine, which appears to be a regulator of protein turnover in muscle),[28] but alanine plays a prominent role analogous to lactate in the Cori cycle.[25,26] The alanine cycle provides the mechanism for the recycling of a fixed supply of glucose and the effective transportation to the liver of amino acid nitrogen derived from muscle breakdown. Because muscle, unlike the liver, is incapable of synthesizing urea, most of the amino nitrogen from protein breakdown is transferred to pyruvate to form alanine. The alanine enters the blood and is taken up by the liver. The amino groups are removed to form urea, and the resulting pyruvate is converted to glucose. The newly synthesized glucose is secreted into the blood, taken up by the muscle, and catabolized to pyruvate to reseed the alanine cycle.[22]

During physical activity and exercise, there are incremental increases in the glucose requirement by the heart and skeletal muscle that require protein catabolism. Although much of the lactate produced by anaerobic metabolism of glucose and glycogen is resynthesized to glucose by the liver via the Cori cycle, the need for glucose is increased, because there is a net loss due to urinary excretion of lactic acid and metabolic inefficiency. Conversely, the energy for resting heart and skeletal muscle is met primarily by oxidation of fatty acids and acetoacetate (ketone). Therefore, during fasting, cannibalized protein reserves are directly related to the degree of physical activity.

Specific physical changes during fasting include decreases in body weight, pulse,[3,18,29] and blood pressure (BP),[3,18,30,31] and a drop in the basal metabolic rate by about 1% per day until stabilizing at about 75% of normal.[31] Other cardiac adaptations noted on an electrocardiogram present as sinus bradycardia, decreased QRS complex and T-wave amplitude, elongation of the QT interval, and shifts to the right of the QRS and T-wave axes. These changes return to normal with return to food,[3,29,31,32] similar to those animals that have prescribed adaptive mechanisms and hibernation cycles.

RESEARCH

Research into fasting has been reported since 1880, with the earliest record of therapeutic fasting in the medical literature appearing in 1910. The earliest research was primarily observational, as physiologic and metabolic changes were recorded while an individual fasted—Tanner (40 days in 1880),[33] Jacques (30 days in 1887 and 40 days in 1888),[34] Penny (30 days in 1905),[35] and Levanzin (31 days in 1912).[18]

In 1923, the classic *Fasting and Undernutrition* provided in-depth analysis of animal and human physiologic changes and reactions during fasting by Morgulis at the University of Nebraska.[30] In 1950, Ancel Keys[3] at the University of Minnesota compiled two volumes entitled *The Biology of Human Starvation* describing the detailed observations of 32 volunteers who fasted for up to 8 months with comparisons to food deprivation observations made during the Second World War. Perhaps the most important observation was that fasting did not cause vitamin or mineral deficiencies. Related starvation research in developing countries noted that those who fasted completely lived longer than those on protein-deficient diets.[16]

Since these groundbreaking works, published clinical studies on therapeutic fasting have demonstrated benefit in almost every organ system. The following is a partial list of diseases and conditions that are beneficially influenced by fasting: chemical poisoning, cardiovascular disease and hypertension, diabetes, epilepsy, obesity, pancreatitis, and immune/inflammatory conditions (all expanded upon), as well as asthma, lumbago, depression and psychosomatic diseases, neurogenic bladder, irritable bowel syndrome, dysorexia nervosa (impaired or deranged appetite),[36] neurosis and schizophrenia,[37] parasites,[38] duodenal ulcers,[39] uterine fibroids,[40] varicose ulcers,[41] thrombophlebitis,[42] eczema,[3,43] and psoriasis.[3,44,45]

Appendicitis

A case report, published in 2011, of a patient advised of mainstream treatment for appendicitis refused surgery to try medically supervised water-only fasting. Pre-fasting ultrasound confirmed inflammatory dilation of the appendix, which was found to be relieved post-fasting by negative clinical and ultrasound findings with no return of symptoms at 2-year follow-up.[46]

Chemical Poisoning

Another encouraging finding for the use of fasting was published in the *American Journal of Industrial Medicine* in 1984. This study involved patients who had ingested rice oil contaminated with polychlorinated biphenyls. All patients reported improvement in symptoms, and some experienced "dramatic" relief, after undergoing 7- to 10-day fasts.[47] This research supported past studies conducted by Inamura with polychlorinated biphenyls poisoned patients and suggested a detoxification effect of fasting.

Cardiovascular Disease

Studies of the effects of fasting on patients with heart disease began in the early 1960s. Duncan et al[44] noted improvements in hypertension and chronic cardiac disease. Others also found fasting to be beneficial in heart disease: Gresham,[48] Lawlor,[42] Imamura,[47] and Vessby.[49] Improvements noted included reductions in serum triglyceride values, BP, atheromas, and total cholesterol levels; increased ratio of high-density lipoprotein cholesterol to total cholesterol; and alleviation of congestive heart failure.[3,24,48,50-53]

In the June 2001 issue of the *Journal of Manipulative and Physiological Therapeutics*, Goldhamer et al[54] reported on a study involving medically supervised water-only fasting in the treatment of hypertension. In this evaluation of 174 consecutive patients with high BP, all patients were able to achieve BP sufficient to eliminate the need for medication, and more than 90% became normotensive. In patients with Stage III hypertension (systolic BP greater than 180 mm Hg) the average reduction in systolic BP exceeded 60 points. This is the largest effect ever published in the scientific literature. Nine months later, Goldhamer et al[55] reported on a study involving 68 consecutive patients with borderline high BP. The average ending BP in these subjects was 99 mm Hg systolic/67 mm Hg diastolic. In a letter to the editor published in *Journal of Alternative and Complementary Medicine* in December 2002, Goldhamer[56] described initial results in 30 patients with high BP participating in a residential health education program that included the supervision of water-only fasting for an average of 14 days. BP, weight, and cost of treatment and medications were compared for the year before and the year after fasting. Preliminary data demonstrated sustained clinical improvement in terms of BP reduction and weight reduction and an average reduction in combined medical and drug costs of almost $2700 per year per subject.

Diabetes

Guelpa recorded the benefits of fasting in type 2 diabetes and gout as well as in inflammation and after surgery.[57] The treatment of diabetes with fasting was further explored by Allen in 1915. He noted that rest and fasting usually stopped glycosuria, and he also observed improvements in gangrene and carbuncles.[58] In 1950, Keys also noted improvement in diabetic patients.[3] Over the last 25 years, type 2 diabetics have successfully fasted, with subsequent reduction or elimination of required medications through successful long-term follow-up, given appropriate lifestyle maintenance post-fasting.[59]

Epilepsy

The treatment of seizures through fasting began in the early 1900s in France by Guelpa and Marie.[60] In 1924, Hoeffel and Moriarty[61] described fasting's beneficial effects in epilepsy. In 1928, concurring with other researchers, Lennox[62] found that the induction of ketosis via fasting decreased the duration, severity, and number of seizures.

Immune and Inflammatory Disorders

The beneficial effect of fasting on certain autoimmune diseases was reported in *Lancet* in 1958. The researchers found that fasting shortened the early stages of acute glomerulonephritis (reduced glomerular filtration rate, high BP, and edema), thus improving prognosis. They concluded that "all patients with acute glomerulonephritis should fast."[63] Other autoimmune diseases that have responded to fasting are rosacea, systemic lupus erythematosus, chronic urticaria, and colitis.[40,64,65]

The subject of arthritis and fasting has received substantial attention in the scientific literature, with most of the research coming from Scandinavia. Scientists documented the anti-inflammatory effects of fasting with observations of decreases in the erythrocyte sedimentation rate (ESR), arthralgia, pain, stiffness, and need for medication.[43,66-72] Consistent with those findings, a 1984 U.S. study of 43 patients with definite or classic rheumatoid arthritis found significant improvements in grip strength, pain, swelling of proximal interphalangeal joints, ESR, and functional activity after a fast of 7 days.[69]

A strong link between arthritis and food intolerance has been revealed through fasting (see also Chapter 205). The diminution in symptoms of rheumatoid arthritis during fasting may be due to the decrease in gut permeability that accompanies fasting,[68] which would reduce the absorption of antigenic molecules into the blood from the gastrointestinal tract. In a 1984 study in *Bulletin on Rheumatic Diseases*, Panush[73] proposed the following theories: (1) nutritional modification might alter immune responsiveness and thereby affect manifestations of rheumatic diseases, and (2) that rheumatic disease may be a manifestation of a food allergy or hypersensitivity.

Fasting, in conjunction with food challenging, is now being used as a diagnostic test to determine food intolerances. Patients fast for a minimum of 4 days, and then individual foods are given to determine whether a reaction occurs. This method correlates well with skin prick and radioallergosorbent testing. A letter in a 1984 *Lancet* issue states, "When food avoidances prevent headaches, [irritable bowel syndrome], arthralgia and depression, it is more effective and less costly than traditional treatment and the observation also throws light on the etiology of the disorder."[74]

Obesity

Fasting for obesity has probably received more attention in the scientific literature than any other aspect. The earliest studies were conducted by Folin and Denis,[50] who in 1915, advocated short fasts as a safe and effective way to lose weight. Bloom,[75] Duncan et al,[44,45] Drenick et al,[51,76] and Thompson et al[52] published numerous works on the use of short and long fasts in obesity. Perhaps the most famous study on obesity appeared in the *Postgraduate Medical Journal* of 1973, which reported the experience of a 27-year-old man who fasted without complications for 382 days and lost 276 pounds.[53]

In general, initial weight loss during fasting is approximately 0.30% of body weight per day, with a gradual decrease to 0.10% per day after 30 days. The initial weight lost is primarily that of water, glycogen, and salt. For every pound lost, the body loses approximately 140 g of protein and 250 g of fat.[24]

Although fasting is very effective for weight reduction, fasting alone, without counseling and other lifestyle modifications, does

not ensure long-term maintenance of the lower body weight. This fact is well documented in a study of 121 obese patients who were monitored for 7.3 years after fasts that averaged 2 months. After 2 to 3 years, 50% of patients returned to their pre-fast weights, and by the end of the study, 90% weighed the same as before their fasts.[77]

Pancreatitis

In a 1984 randomized clinical trial (n = 88), fasting was determined to be the treatment of choice for patients with acute pancreatitis. The researchers suggested that "fasting alone be initially used as the simpler and more economical therapy." They found that "neither nasogastric suction nor cimetidine offer any advantage over fasting alone in the treatment of mild to moderate acute pancreatitis of any etiology."[78]

APPLICATION

Therapeutic fasting is best conducted under supervision at an inpatient facility. Such facilities will exercise care in terminating a fast and supervising post-fast recuperation, monitor laboratory values in light of fasting physiology, review imaging as necessary, and demonstrate prudence when using adjunctive therapies during fasting. Several facilities now exist in the United States, Canada, England, and Australia, and these centers follow the standards of care and principles of ethics established by the IAHP.[15]

It is important to recognize that therapeutic fasting can be viewed to have three stages or phases. Stage I fasting (also called early or turbulent fasting) lasts up to 7 days, as the body adapts to fasting physiology with the common symptoms of excessive cellular waste or slowed elimination—malaise, headaches, and muscle aches—that are generally transitory, but can be disconcerting. Only the most genetically capable detoxifiers or the least toxic individuals glide comfortably through this stage. After passing through this period, it is more "the mind" rather than "the body" that continually obsesses on eating. Stage II, or balanced fasting, is the most significant fasting stage, as remodeling of tissues promotes healing. It can last for weeks to months. Patients often experience one or more "healing crisis" (where chronic conditions/symptoms become acute) and/or go through less significant detoxification reactions. Stage III fasting is often called depletion fasting (or simply "starvation") as the body can no longer effectively or efficiently mobilize fat stores. Although many old texts refer to "fasting to completion" (i.e., exhaustion of nutrient reserves), this practice is now uncommon and not usually necessary,[79] as serial fasting after appropriate refeeding appears to be a safer alternative.

When we fast, we recreate the natural occurrence of our ancestors when a "late spring" meant depleted food reserves followed by unintentional fasting while waiting for the snow to melt and the new shoots to rise for sustenance. Today, voluntary and attended therapeutic fasting provides the opportunity to mobilize or peel back the layers of our structural and functional adaptations within and between cells that are no longer required or beneficial. Therefore, like an onion that may have a superficial bruise, during a fast, the body "peels the onion" by deconstructing the buttressing ("the disease") back to a healthy vital core or foundation that health can be built upon. Thus, a health promoting diet is pivotal to growth and maintenance of healing, and further, even with shorter annual fasts, allows less symptomatology and the ability to retain vitality throughout the year.[59]

Unfortunately, determining optimal fast length is difficult to predict and includes many factors, including size of reserves, individual metabolism, financial limitations, work schedule, severity of disease, age, and sex. This decision is based on all factors, especially the patient's mental state. Experience shows that extending a fast beyond a healing crisis (or noteworthy detoxification reaction) provides significant clinical benefit where stopping midcourse suppresses healing until the same symptomatology appears, albeit earlier, in the course of a subsequent fast. Overall, "[the] doctor will look for good practical recovery where patient is symptom free and signs of regeneration are present."[79]

General Principles

The use of a low salt, vegan, high fiber, low fat, low protein, and low sugar diet before and after fasting has been found beneficial and avoids complications of fasting. This diet also promotes pre-fast bowel movements and subsequent post-fast bowel movements that are sooner to evolve, easier to pass, and less problematic. (To commence fasting, bowel movement frequency must be at least daily.) Using broth or fruit and other juices are examples of restricted diets. They do not initiate fasting metabolic processes since they contain carbohydrates, protein, and/or fat. Nonetheless, restricted diets are often useful before and after fasting and for patients in whom a healing crisis develops during a fast or when a fast is contraindicated.[80] In most cases, a fast is superior to the restricted diet because (1) hunger almost totally disappears,[3,44] (2) ketosis occurs more quickly and efficiently,[3,44] (3) famine edema does not occur,[3] (4) sodium diuresis is more pronounced,[75] (5) weight loss is more dramatic and is from fat rather than protein stores, (6) healing time is shorter, and (7) patient strength may be greater.[81]

Individual variation (predominantly diet and lifestyle history) determines the level of comfort experienced through the mobilization process of fasting from the initial transition of utilizing energy stores from digestion and stored glycogen to the energy generation from gluconeogenesis and the β-oxidation of triglycerides.

Rest is a most important aspect of the fast and patients may nap throughout the day. Less sleep is common at night, possibly owing to the decreased daily activity and the increase in daytime rest.

Exercise while fasting is discouraged. Fuel conservation is necessary to allow maximal healing and the avoidance of unnecessary gluconeogenesis.[81,82] The body utilizes certain muscle proteins early in a fast, thus initiating the natural restriction of activity. Short walks or light stretching is permissible, but intense exercise inhibits repair and elimination. In serious chronic disease, an excess of activity has been suspected as cause of death during fasting.[83] Even moderate activity can double caloric utilization.[84]

Sunlight is important for general health during fasting, and patients should try to obtain 10 to 20 min/day. Sun dehydration does promote orthostatic hypotension and subsequent injury from falls. An increase in heart rate of 10 to 15 beats/min may indicate excessive sun exposure.

Pure water (distilled, filtered, or reverse osmosis) is recommended.[81,82] Researchers of fasting obese individuals often recommend 3 L/day,[24] and 64 to 96 oz/day is commonly adequate, although upwards of 160 oz is commonly ingested without affecting serum sodium status. Although increased water intake will allow for less detoxification reactions during days of greater mobilization, excess consumption will cause electrolyte depressions that are clinically significant and require refeeding. Physiologically, the body is able to modulate "available water" through reduced

obligatory water excretion (owing to lower excretion of urea, the major osmotic solute) and by access to released water from catabolized fat.[16]

Laboratory tests such as a complete blood count and serum chemistry screen are usually performed weekly and others are performed as necessary. Regular urine tests are performed and vital signs are checked daily.[77,85]

Upon refeeding there is a sudden shift from a low insulin, fat-burning metabolism to a high insulin, glucose-based state. As the plasma insulin rises, potassium, phosphate, and magnesium are driven intracellularly and sodium extracellularly, acting to expand and dilute the circulating volume. Sodium restriction during refeeding therefore should be emphasized to not precipitate dilution, edema, or acute heart failure.[86]

LABORATORY VALUES

Most laboratory values for body fluids during fasting do not follow specific patterns, but are unique to the individual and the disease process.[32,52] Assessment of a fasting patient's progress is based not on a sign or symptom, but on the total clinical picture. Although specific predictions of laboratory values during fasting are not possible, some general observations have been made.

Urinalyses may be difficult to interpret during fasting, because the body discards considerable waste via the kidneys.[77] It is not uncommon to see various types of casts, red blood cells, white blood cells (WBC), bilirubin (+1 to +2), protein (trace, +2), and ketones (+4), and, if liver disease is present, urobilinogen elevation. Trace leukocytes and blood are common incidental findings, particularly in women. Specific gravity is commonly elevated (possibly to 1.035), a finding that may reflect inadequate hydration.[85]

Complete blood counts usually show no significant change.[77] Low hemoglobin and hematocrit values have been observed,[42,85,87] requiring rule out of hemolysis or hemorrhage,[88] whereas elevations in hematocrit, hemoglobin, and red blood cell count usually indicate reduced hydration.[77,85,89] WBC counts are usually unchanged or decrease slightly with fasting; however, infection may cause an increase. Further, WBCs may increase, particularly if levels are low before fasting.[88]

All of the electrolytes have reductions over the long term as the body's mobilized stores are lost, but it is significant to note the ability to redistribute stores even with only distilled water during extended fasts. Serum electrolyte levels are not good indicators of tissue stores, but they are considered the most important blood values during fasting,[88] because they usually do not change significantly during fasting unless there is a concern that needs management.

The total body store of sodium is 83 to 97 g (of which 65% is exchangeable), and that of potassium is 115 to 131 g (of which 98% is exchangeable). The typical daily dietary intake of sodium is 3 to 7 g, and of potassium, 3 to 5 g.[90] During early fasting, the body loses 150 to 250 mEq (3.5 to 5.8 g) of sodium and 40 to 45 mEq (1.6 to 1.8 g) of potassium a day; later, these values drop to 1 to 15 mEq (0.02 to 0.35 g) and 10 to 15 mEq (0.4 to 0.6 g), respectively. Serum potassium usually decreases (but may become elevated) and values less than 3 mEq/L or above 6 mEq/L often require breaking of the fast. The electrolytes calcium and chloride are usually stable, but levels often diminish, especially if vomiting is present.[88]

Liver enzyme values may increase considerably if liver disease is present and may rise even if liver disease is not present. Triglyceride, cholesterol, and uric acid levels usually rise during fasting,[85,91,92] indicating mobilization of tissue stores. Post-fast values often show a decrease from pre-fast values,[49,61,91] but lipid panels will not show a new baseline value until 4 to 6 weeks post-fast. The serum protein value usually declines with fasting. Pancreatic lipase and amylase values also usually drop with fasting.[88]

A rise in blood urea nitrogen (BUN) value may occur, but some authorities have observed a decrease.[3,62,42] The serum creatinine value may be elevated[49,85] or may remain stable,[93] and depression requires prompt retesting or fast termination. Closely monitor creatinine for elevations, particularly in those with renal compromise. Blood glucose values drop in most patients,[43,58,61,62] possibly below 30 mg/dL. If the blood glucose value is low before fasting, it may rise after fasting. ESR and C-reactive protein usually drop after fasting, although they may rise during the fast.[68,70,85]

Hormonal changes during fasting typically consist of decreases in insulin[16,20,23,32,94] and thyroid hormone levels.[29,32,95] Increased levels of growth hormone,[29,32,95] cortisol,[89] glucagon,[16,20] plasma norepinephrine,[96] serum melatonin,[96] and certain prostaglandins (in animals) usually occur.[97] In contrast, a decrease in growth hormone is usually found in obese individuals.[32] In one study conducted in 10 postmenopausal women who underwent short-term fasts, no significant changes in adrenal hormones, androgens, serum and urinary estrogens, plasma epinephrine, or dopamine were recorded.[96]

After a 44 day fast, the following changes were noted in less commonly ordered bloodwork—elevations: cortisol, somatostatin, insulin-like growth factor–binding protein 1; very low levels: leptin, ghrelin, insulin-like growth factor 1; normal values: peptide YY, agoutirelated peptide, α-melanocortin-stimulating hormone, neuropeptide Y, and pro-opiomelanocortin.[98]

Adjunctive Care

Some medical studies recommend supplementation with vitamins, fruit and vegetable juices, acaloric fluids (coffee, tea, etc.), and drugs while the patient is "fasting." These practices have not been shown to produce any advantage, and serious problems have sometimes occurred, especially when nonessential medication was permitted.

Dietary Supplements

Loss of minerals or vitamins is usually not a concern, and deficiencies during fasting are rare. Problems such as nausea and indigestion were reported when mineral and vitamin supplements were taken during fasting.[76,93] For example, it is well known that nicotinic acid supplementation inhibits the release of free fatty acids from adipose tissue.[24] In one patient in whom vitamin deficiency was reported in the medical literature, the actual fasting protocol was not described; in addition, the patient's physical activity was not restricted and oral medication for intercurrent illness was maintained during fasting.[76] Vitamin and mineral excretion becomes very low after 10 days.

Enemas

Enemas are not usually necessary and do not generally offer any added benefit during fasting.[66] Some authorities have found that enemas also cause discomfort.[81] To help prevent constipation, pre-fast meals of only fresh fruit and vegetables for at least 2 days will assist in establishing proper elimination before the fast is initiated. Lack of bowel movement 3 to 5 days post-fast (particularly on longer fasts) may point to the need for stewed prunes with meals until resolution or an enema becomes necessary.

Hydrotherapy

Constitutional hydrotherapy and sitz baths have been implemented with fasting. Strong treatments, both in frequency and/or temperature interval size, should be limited to early fasting.

Intravenous Therapy

Intravenous administration requires much care and is best avoided entirely, except for emergent conditions. Saline should be avoided due to plasma expansion and edema, which has precipitated acute heart failure. Glucose, in contrast, should be accompanied by vitamin B_1 and B_6 co-administration to avoid acute thiamine deficiency and lactic acidosis.[99]

Pharmaceuticals

The primary concern of fasting medicated patients is potentiation of pharmaceutic action during fasting physiology. Specifically troubling is the potentiation of the known mechanism of action, urinary/hepatic metabolism, as well as known side effects and adverse events. Appropriately removing pharmaceuticals allows for ease of clinical assessment while ensuring patient safety. Successful fasting has been continually repeated while maintaining some hormonal medications (insulin, thyroid, and reproductive organ hormones, often at reduced dosage), but not with adrenal maintenance.

CONTRAINDICATIONS

Contraindications to fasting are few, and each case must be judged individually, because no two cases are alike. For example, an inexperienced practitioner may assume that emaciated patients should not fast, but about this issue Shelton[81] had the following to say: "Extreme emaciation: In such cases a long fast is impossible. A short fast of 1-3 days may be found beneficial, or a series of such short fasts with longer periods of proper feeding intervening may be found advisable."

Contraindications to fasting include severe anemia, porphyria, and serious malnutrition. Individuals with a rare fatty acid deficiency of the enzyme medium-chain acyl-CoA dehydrogenase should also avoid fasting.[40]

The fasting of children and pregnant women is controversial. Although a short fast is appropriate for the sick child who does not want to eat, fasting in a pregnant woman may be strongly contraindicated; ketosis in pregnant diabetic women is known to be associated with fetal damage. Although this association is commonly recognized, the fact that this information has come only from research of diabetic pregnant women is not as widely known.[100] There appear to be no studies of the effects of nondiabetic ketosis on fetal development. Doctors (e.g., Shelton, Benesh, Sidwha, and Burton) with considerable experience of fasting pregnant women during all three trimesters have found no adverse effects with fasts of a few days to 2 to 3 weeks. Although the fasting of pregnant women appears from clinical observation to be safe, definitive pronouncement cannot be made until careful research is performed (such as a controlled retrospective analysis of existing cases).

Fasts for children and pregnant women should be shorter and should be meticulously supervised by an experienced doctor. In *The Science and Fine Art of Fasting*, Shelton[81] wrote, "Few infants require more than 2-3 days of fasting. … I have never hesitated to permit a sick infant to fast and I have yet to see one harmed by it." Regarding pregnancy he said, "The author would object to a long fast in chronic 'disease' during this period. There can, however, be no objection to a short fast."[81]

It is well recognized that fasting during lactation is not generally advised, because milk flow is halted by fasting and is difficult to resume.[81] Although fasting is considered inappropriate in renal insufficiency,[24] we have seen patients with 65% renal function return to normal as a result of fasting and dietary management.

With regard to fasting contraindications in general, Burton[79] stated:

> *I have found few health problems which are absolute contraindications to fasting. In my experience, if the need is evident, the only genuine contraindication is fear…. As for the other conditions often mentioned, e.g. kidney disease, heart impairment, [tuberculosis], etc., they merely require extreme caution, because of the limits imposed by pathology, but they are not inexorable contraindications.*

Supervised fasting as a therapeutic procedure is generally safe and effective. The incidence of death at fasting institutions is low, a fact that is promising because many of the patients have serious chronic diseases and have exhausted other therapeutic options. Of the hundreds of cases of fasting described in the scientific literature, only seven cases of death were reported before 1985.[36,83,101-104] In all cases, the patients had serious chronic disease before fasting, and in five of the seven cases, drugs were given to the patients while fasting; in the other two, no description of protocol was provided.

There is no evidence in the scientific literature to suggest that fasting itself can be considered a cause of death. Death during fasting indicates that the remedial efforts of the body have been overpowered by the pathologic process. This situation occurs in serious disease, whether the patient is eating or fasting. In examining the fallacy of attributing the cause of death to fasting, Stewart and Fleming[105] wrote, "Fasting short of emaciation is not hazardous; if death results, reasons other than those of the fast should be considered before concluding that all supervised fasts should be discouraged."

SIDE EFFECTS

Side effects of fasting are rarely serious, but fasting may uncover disease and reveal weaknesses that were previously subclinical.[44] Discomfort during fasting may be due to withdrawal from stimulants, hypoglycemia, acidosis, elimination of wastes, and enhancement of repair. Patients may experience headaches, insomnia, skin irritations, dizziness, nausea, coated tongue, body odor, aching limbs, palpitations, mucous discharge, and visual and hearing disturbances. Hair growth is usually arrested, and skin may become dry and scaly. Most signs and symptoms are usually brief as the body works to remove the disease.

In certain cases, complications occur that may necessitate breaking the fast early. Examples of such conditions are as follows:

- A sudden drop in BP (possibly due to peripheral circulatory collapse)
- Delirium
- Prolonged hypothermia
- Rapid, slow, feeble, or irregular pulse
- Extreme weakness
- Dyspnea
- Vomiting and diarrhea leading to dehydration
- Gastrointestinal bleeding
- Hepatic decompensation
- Renal insufficiency
- Severe gout
- Cardiac arrhythmias
- Emotional distress

Fasting elevates serum uric acid values and uric acid excretion, and if fluid intake is insufficient, gout or renal stones may be precipitated.[24,106]

A few studies have discussed the development of Wernicke encephalopathy during prolonged fasting, but because it rarely occurs during therapeutic fasting, it is difficult to determine whether the condition is related to methodology. It is important, however, to acknowledge the importance of utilizing B vitamins, especially thiamine, when any fast is broken with intravenous glucose.[107,108] The decision to terminate the fast should be based on the complete clinical picture and not on an isolated sign or symptom.

CONCLUSION

The vast potential of therapeutic fasting is only beginning to be realized, although results have been recorded since the early 1900s.[109-114] Considerable empiric study has been accomplished, and fasting is generally a safe, economical, and effective therapy. Extensive research revealed pervasive and important effects, including the enhancement of immune system function.[70,89,115-118] Unfortunately, a lot of prejudice exists. When we fast or assist another in fasting, perhaps the deepest human instinct is struck at depth—our need to eat, to survive, to exist. This often prevents otherwise intelligent and open-minded individuals from considering the facts regarding fasting and its unique benefits to human evolution and even health. There have been tragic deaths from fasting (almost exclusively inappropriately supervised), but fasting is not synonymous with starvation as our "instinctual self" would like to have us believe. Individual centers have successfully supervised the fasts of over 7000 people without fatalities over the last 27 years,[59] and as more appreciate the "healing power of nature," this therapy will become more mainstream.

INTRODUCTION

For almost as long as historic records have been kept, glandular therapy has been an important form of medicine. The basic concept underlying the medicinal use of glandular substances from animals is that "like heals like." For example, if the liver needs support or a patient is suffering from liver disease, then he or she may benefit from eating beef liver. Modern glandular therapy, however, primarily involves the use of concentrated glandular extracts.

A gland is defined as a secretory organ. The internal secretory organs of the body are called endocrine glands. These ductless glands secrete hormones directly into the bloodstream. The glands known to have endocrine function include the pineal, pituitary, thyroid, parathyroid, thymus, adrenal, pancreas, and gonads (testes or ovaries). Although not technically glands, it is common to refer to other organs of the body as glandulars when they are used in glandular therapy. For example, tissue extracts of heart, spleen, prostate, uterus, brain, and other tissues are often used in glandular or organotherapy.

Research has shown that certain glandular preparations and hormones are quite effective when taken orally. A number of glandular preparations are effective orally because of active hormone or enzyme content (e.g., thyroid, adrenal cortex, and pancreatin preparations). A good deal of literature supports pharmaceutical grade liver, aorta, and thymus extracts, and some support exists for pituitary, spleen, orchic (testes), and ovarian extracts as well. However, despite this scientific support, many still question the effectiveness of glandular products on human health.

A key challenge to the use of glandulars is the lack of widely accepted standards for extraction and quantification. Each manufacturer of a glandular product claims its method of extraction is the most ideal. However, the majority of these contentions are based on theoretic or philosophic grounds, not on research or clinical results. No quality control procedures or standards are enforced in the glandular industry. It is left up to the individual company to adopt quality control and good manufacturing procedures. Nonetheless, many glandular preparations available in the U.S. marketplace appear to be effective.

METHODS OF MANUFACTURE OF GLANDULAR PREPARATIONS

It is critical that properly processed glandular material be used, since the biologically active material such as enzymes, soluble proteins, natural lipid factors, vitamins, minerals, and hormone precursors are destroyed or eliminated if the product is not prepared properly.

Most glandular products are derived from beef (bovine) sources, the exception being pancreatic extracts, which are most often derived from pork (porcine) sources. The four most widely known methods of processing are the azeotrophic method, salt precipitation, freeze-drying, and predigestion.

The Azeotrophic Method

The azeotrophic method begins by quick freezing the material at well below 0°F, and then washing the material with a solvent (such as ethylene dichloride) to remove the fatty tissue. The solvent is then distilled off, and the material is dried and ground into a powder so that it can be placed in tablets or capsules. Although the azeotrophic

method eliminates the problem of fat-stored toxins like pesticides and healthy metals, unfortunately, it also removes fat-soluble hormones, enzymes, essential fatty acids, and other potentially beneficial materials; in addition, traces of the solvent still remain.

The Salt Precipitation Method

This method involves the maceration of fresh glandular material in salt and water. Because the salt increases the density of the water-soluble material, when the mixture is centrifuged, the lighter fat-soluble material can be separated out. The material is then dried and powdered. The benefit with the salt precipitation method is that no toxic solvents are used to separate the fatty material. The downside is the increased salt content of the product.

Freeze-Drying

The freeze-drying process involves quickly freezing the glandular material at temperatures of –40°F to –60°F and then placing the material into a vacuum chamber, which removes the water by direct vaporization from its frozen state (hence, the term freeze-drying). The benefit of freeze-drying is that it contains a higher concentration of unaltered protein and enzymes, as well as all of the fat-soluble components. Because the fat is not removed, it is critical that the glands are derived from livestock that have grazed on open ranges not sprayed with pesticides or herbicides. The animals must also be free from antibiotics, synthetic hormones, and infection.

Predigestion

The predigestion method employs plant and animal enzymes or some other method to partially digest or hydrolyze the glandular material. The partially digested material is then passed through a series of filtrations to separate out fat-soluble and large molecules. The purified material is then freeze-dried. This method of extraction is best for glandulars (such as the liver and thymus) where the polypeptide and other water-soluble fractions are desired.

SPONGIFORM ENCEPHALOPATHY

Bovine spongiform encephalopathy (BSE), also known as mad cow disease, is a transmissible, slowly progressive, degenerative, fatal disease affecting the central nervous system of adult cattle. The transmissible agent in BSE is a modified form of a normal cell surface component known as a prion protein. Unlike infectious organisms, prions are resistant to common treatments, such as heat and digestive secretions. Eating the meat of an animal with BSE may lead to a disease similar to BSE in humans called variant Creutzfeldt-Jakob disease.

BSE was first reported among cattle in the United Kingdom in 1986 and has been a major concern since then. The outbreak in the United Kingdom may have started from the feeding of scrapie-contaminated sheep meat-and-bone meal to cattle. Scrapie is a disease of sheep that is related to BSE in cattle. Evidence is strong that the outbreak in cattle was amplified in the United Kingdom by feeding rendered bovine meat-and-bone meal to young calves.

BSE has been reported in cattle throughout Europe. There has been a single case in Canada and, most recently, in the United States from a cow imported from Canada. Wild game in the United States such as deer and elk have been affected with a similar disease known as chronic wasting disease. The reason American cattle have been spared may be due to the active surveillance and import measures taken by the U.S. Food and Drug Administration (FDA) and the U.S. Department of Agriculture (USDA).

The USDA has restricted the importation of live ruminants, such as cows and sheep, and food products from these animals from BSE countries since 1989, and from all European countries since 1997. In addition, the FDA prohibits the use of most mammalian protein in the manufacture of animal feeds given to ruminants because this kind of feeding practice is believed to have initiated and amplified the outbreak of BSE in the United Kingdom.

To reduce the risk of ingesting beef with BSE, it is critical to use products manufactured under the following guidelines:

- The June 2000 European Commission Decision regulating the use of material presenting risks for BSE
- A "Certification of Suitability" by the European Directorate of Quality of Medicines to ensure the highest quality, pharmaceutic grade material is being used
- The FDA's guidelines for sourcing and processing of bovine material

EVIDENCE FOR INTACT PROTEIN ABSORPTION

There is now considerable evidence that large macromolecules pass intact from the normal human gut into the bloodstream. In some instances, the body appears to recognize which molecules it needs to absorb intact and which molecules it needs to break down into smaller units. This phenomenon may help to explain the effectiveness of glandular therapy.

Numerous whole proteins have been shown in human and animal studies to be absorbed intact into the bloodstream after oral administration.[1-7] These include human albumin and lactalbumin, bovine albumin, ovalbumin, lactoglobulin, ferritin (molecular weight 500,000), chymotrypsinogen, elastase, and other large molecules.

Furthermore, proteins and polypeptides, as well as various hormones that are absorbed intact from the gut, have been shown to exert effects in target tissues. For example, in addition to thyroxine or thyroid hormone and cortisone, several peptide hormones are known to be biologically active when administered orally, including luteinizing hormone-releasing factor and thyrotropin-releasing hormone.[8,9] Even insulin has been shown to be absorbed orally under certain circumstances (e.g., in the presence of protease inhibitors or hypertonic solutions in the intestines).[10,11]

These data indicate that at least some of the larger molecules in glandular products are absorbed intact to induce physiologic effects, particularly polypeptides, which exert hormone or hormone-like action.

CLINICAL APPLICATIONS

An adequate body of research now exists to support the use of orally administered glandular extracts. The following is a brief discussion of several glandular preparations and their use. Table 38-1 lists the primary conditions responding to glandular therapy.

Adrenal Extracts

Oral adrenal extracts have been used in medicine since at least 1931.[12] Adrenal extracts may be made from the whole adrenal gland or just from the adrenal cortex. Whole adrenal extracts (usually in combination with essential nutrients for the adrenal gland) are most often used in cases of low adrenal function, presenting as fatigue, inability to cope with stress, and reduced resistance. Because extracts made from the adrenal cortex contain small

TABLE 38-1 **Therapeutic Uses of Glandular Extracts**

EXTRACT	CLINICAL APPLICATIONS
Adrenal extracts	Chronic fatigue Asthma Eczema Psoriasis Rheumatoid arthritis
Aortic glycosaminoglycans	Cerebral and peripheral arterial insufficiency Venous insufficiency and varicose veins Hemorrhoids Vascular retinopathies, including macular degeneration Postsurgical edema
Liver extracts	Chronic hepatitis Chronic liver disease
Pancreatic extracts	Pancreatic insufficiency Cystic fibrosis Inflammatory and autoimmune diseases such as rheumatoid arthritis, scleroderma, athletic injuries, and tendinitis Cancer Infections
Spleen extracts	After splenectomy Immune potentiation Infection Cancer Hyposplenia Celiac disease Dermatitis herpetiformis Ulcerative colitis Rheumatoid arthritis Glomerulonephritis Systemic lupus erythematosus Vasculitis Low white cell counts Thrombocytopenia
Thymus extracts	Recurrent and chronic viral infections, such as chronic fatigue syndrome, respiratory infections, AIDS, acute hepatitis B infection Cancer patients with immune depression from chemotherapy or radiation Asthma, hay fever, eczema, and food allergies Autoimmune disorders, such as rheumatoid arthritis, lupus erythematosus, and scleroderma
Thyroid extracts	Hypothyroidism

AIDS, acquired immunodeficiency syndrome.

amounts of corticosteroids, they are typically used as a "natural" cortisone in severe cases of allergy and inflammation (e.g., asthma, eczema, psoriasis, rheumatoid arthritis).

Dosage

The dosage of adrenal extract depends on the quality and potency of the product. The best measure of an effective dose for a preparation may be the level of stimulation (irritability, restlessness, and insomnia) the patient experiences. When prescribing adrenal extracts, start at one third of the recommended dosage on the label and slowly increase the dosage every 2 days until a stimulatory effect is noted. Once this effect is noticed, reduce the dosage to a level just below the level that produces stimulation.

Aortic Glycosaminoglycans

A mixture of highly purified bovine-derived glycosaminoglycans (GAGs) are naturally present in the aorta, including dermatan sulfate, heparan sulfate, hyaluronic acid, and chondroitin sulfate; related hexosaminoglycans have been shown to protect and promote normal artery and vein function. More than 50 clinical studies have shown an orally administered complex of aortic GAGs to be effective in a number of vascular disorders, including the following:

- Cerebral and peripheral arterial insufficiency
- Venous insufficiency and varicose veins
- Hemorrhoids
- Vascular retinopathies, including macular degeneration postsurgical edema[13-22]

Significant improvements in both symptoms and blood flow have been noted.

In addition, aortic GAGs have many important effects that interfere with the progression of atherosclerosis, including prevention of damage to the surface of the artery, formation of damaging blood clots, migration of smooth muscle cells into the intima, and formation of fat and cholesterol deposits, as well as lowering total cholesterol levels while raising high-density lipoprotein cholesterol.[23-27]

Dosage

The dosage of the mixture of highly purified bovine-derived GAGs naturally present in the aorta is 100 mg/day. Similar, but not nearly as impressive, results in the treatment of atherosclerosis have been noted with chondroitin sulfate at a daily dose of 3 g (1 g, three times daily).[28]

Liver Extracts

Beef (bovine) liver extracts and concentrates are a rich natural source of many vitamins and minerals, including iron. Liver extracts can contain as much as 3 to 4 mg of heme iron per gram. In addition to its use as a source of iron and other nutrients, hydrolyzed liver extracts have been used to treat chronic liver diseases since 1896. Numerous scientific investigations into the therapeutic efficacy of liver extracts demonstrated that these extracts improved fat utilization, promoted tissue regeneration, and prevented damage to the liver.[29-32] In short, clinical studies demonstrated that oral administration of hydrolyzed liver extracts can be quite effective in improving liver function.

For example, in one double-blind study, 556 patients with chronic hepatitis were given either 70 mg of liver hydrolysate or a placebo three times daily.[32] After 3 months of treatment, the group that received the liver extract had far lower serum liver enzyme levels. Because the level of liver enzymes in the blood reflects damage to the liver, it can be concluded that liver extract is effective in chronic hepatitis via an ability to improve the function of damaged liver cells, as well as prevent further damage to the liver.

Dosage

The dosage is entirely dependent on the concentration, method of preparation, and quality of the liver extract. The highest quality products are aqueous hydrolyzed extracts because they have the

fat-soluble components removed and typically contain more than 20 times the nutritional content of raw liver, including 3 to 4 mg of heme iron per gram.

Contraindication

Liver extracts should not be used in patients experiencing an iron-storage disorder, such as hemochromatosis.

Pancreatic Extracts

Pancreatic enzymes are most often employed in the treatment of pancreatic insufficiency. Pancreatic insufficiency is characterized by impaired digestion, malabsorption, nutrient deficiencies, and abdominal discomfort. Pancreatic enzymes are also used by physicians in the treatment of the following:

- Cystic fibrosis
- Inflammatory and autoimmune diseases like rheumatoid arthritis, scleroderma, athletic injuries, and tendinitis
- Cancer
- Infections

For a full discussion of pancreatic enzymes, see Chapter 111.

Dosage

Full-strength products are preferred to lower potency pancreatin products because lower potency products are often diluted with salt, lactose, or galactose to achieve desired strength (e.g., 4× or 1×). The dosage recommendation for a 10× U.S. Pharmacopoeia (USP) pancreatic enzyme product is 500 to 1000 mg three times a day immediately before meals when used as a digestive aid and at least 20 minutes before meals or on an empty stomach when anti-inflammatory effects are desired.

Pancreatic extracts are generally well tolerated and are not associated with any significant side effects.

Spleen Extracts

As early as the 1930s, orally administered bovine spleen extracts were shown to possess some physiologic action in increasing white blood cell counts in patients with extreme deficiencies of white blood cells, as well as being of some benefit in patients with malaria and typhoid fever.[33-35]

Like thymus extracts, pharmaceutic-grade bovine spleen extracts are currently quite popular in Germany for the treatment of infectious conditions and as immune-enhancing agents in cancer. Spleen tissue extracts may be of benefit in enhancing general immune function, since many potent immune system–enhancing compounds secreted by the spleen are low-molecular-weight peptides. For example, the potent immunostimulants tuftsin and splenopentin are composed of only four and five amino acids, respectively.

Both tuftsin and splenopentin have been shown to exert profound immune-enhancing activity. Tuftsin stimulates macrophages that have taken up residence in specific tissues like the liver, spleen, and lymph nodes. Tuftsin also helps to mobilize other white blood cells to fight against infection and cancer. A deficiency of tuftsin has been associated with signs and symptoms of frequent infections.[36]

Splenopentin, like tuftsin, has also demonstrated significant immune-enhancing effects. Its effects are primarily directed toward enhancing the immune system's response to regulating compounds such as colony-stimulating factors.[37] Colony-stimulating factors, such as interleukin-3, and granulocyte/macrophage colony–stimulating factors stimulate the production of white blood cells. Splenopentin is probably the factor responsible for the results noted in clinical studies during the 1930s in which spleen extracts were used in the treatment of depressed white blood cell counts.

Splenopentin has also been shown to enhance natural killer cell activity.[38] Natural killer cells destroy cells that have become cancerous or infected with viruses and are the body's first line of defense against cancer.

In addition to tuftsin and splenopentin, hydrolyzed (predigested) spleen extracts concentrated for peptides demonstrated impressive immune restorative properties in mice.[39] In one study, mice were exposed to radiation to significantly damage the immune system. Mice treated with the spleen extract recovered within 6 to 8 weeks. In contrast, those treated with a placebo recovered after 10 weeks at the earliest.

The primary clinical uses of spleen extracts are after removal of the spleen and the following conditions associated with low spleen function (hyposplenia):

- Celiac disease
- Dermatitis herpetiformis
- Ulcerative colitis
- Rheumatoid arthritis
- Glomerulonephritis
- Systemic lupus erythematosus
- Vasculitis
- Thrombocytopenia

Spleen extracts may also be useful in the treatment of low white blood cell counts, bacterial infections, and as an adjunct in cancer therapy. Individuals who have had splenectomies or who have low tuftsin levels or autoimmune conditions linked to low activity of the reticuloendothelial system should use spleen extracts.

Because the spleen is difficult to repair, severe spleen trauma usually requires splenectomy to stop the severe hemorrhage. The spleen is also removed in the medical treatment of certain diseases, such as idiopathic thrombocytic purpura and to determine the extent of Hodgkin disease.

Removal of the spleen is associated with an increased risk for infection. This increased risk of infection makes children and adults particularly susceptible to pneumococcal pneumonia. About 2.5% of patients who have their spleen removed die from pneumococcal pneumonia within 5 years of splenectomy. It is often recommended that a child who has undergone a splenectomy receive a pneumococcal vaccine and receive long-term antibiotic treatment. Use of spleen extracts, especially those rich in tuftsin, may be a natural alternative.

Spleen extracts should probably be viewed as a necessary medicine for people who have had their spleen removed. If the thyroid, adrenals, or ovaries are removed, most patients would be prescribed the corresponding hormone. It only makes sense that if the spleen is removed, the body should be supplied with necessary spleen substances like tuftsin and splenopentin.

The increased risk of infection is attributed primarily to a deficiency of tuftsin.[40,41] Tuftsin is produced only in the spleen; without the spleen there simply is no tuftsin in the circulation. Without tuftsin, the body is without one of its key stimulators of the immune system. Individuals without spleens need an outside source of tuftsin, like spleen extracts.

Dosage

Clinically, hydrolyzed (predigested) products concentrated for tuftsin and splenopentin content are preferable to crude preparations. The daily dose should provide 50 mg tuftsin and splenopentin or roughly 1.5 g of total spleen peptides.

No side effects or adverse effects have been reported with the use of oral spleen preparations.

Polyerga

Before the development of manufacturing techniques for human insulin to be used in the treatment of diabetes, the source was insulin isolated from pig pancreas. In Germany, after World War II, there was a shortage of pigs and subsequently a shortage of insulin. A German researcher, Walter Kuhlmey, MD, PhD, subsequently sought to produce insulin from other animal organs, most notably the spleen. In the process, this led to the serendipitous discovery of Polyerga. Kuhlmey found that the pig spleen extract not only had some insulin-like activity, but that it also increased the general sense of well-being and gave people more energy. He named his new product Polyerga (in Latin poly means "multiple" and erga means "power").

Initially, Polyerga had a general use. In 1951, an event changed Polyerga's clinical use. Julia Meir was a patient of oncologist Heinrich Pophanken, MD. She had an advanced cancer of the pancreas. She was considered incurable, and her death was expected shortly. In an effort to ease her pain, lift her fatigue, and stimulate a sense of well-being in Julia, Pophanken gave her Polyerga (via injection). Surprisingly, the dying patient began to recover. Pophanken gave Julia three to six intramuscular injections of Polyerga per week during the first 2 months and then just two injections a week thereafter. In 1954 Julia died of causes unrelated to her cancer. When the autopsy was conducted, the egg-sized tumor in her pancreas had disappeared entirely. This single case history led to the focus of research on Polyerga as a cancer therapy.

Cancer Therapy

Polyerga has been evaluated in several clinical studies in cancer patients. In one of the largest trials, 158 breast cancer patients were divided into two groups. The women in the Polyerga group received injections of Polyerga three times per week, whereas the women in the control group received a placebo injection. In the Polyerga group, the percentage of white blood cells, various parameters of immune function, body weight, and general sense of well-being all improved significantly compared with the control group.[42]

In a double-blind, placebo-controlled study in patients with head and neck cancers, Polyerga was shown to support patients who received the chemotherapy drugs 5-FU and cisplatin.[43] Polyerga was shown to stabilize the levels of lymphocytes. Typically, patients receiving 5-FU, cisplatin, and other chemotherapy drugs experienced a reduction in lymphocytes. This effect was noted in the placebo group but not in the patients receiving Polyerga. In addition, the Polyerga group reported less fatigue and higher energy levels than the placebo group, and there was no weight loss. Prevention of weight loss is a major goal in the support of the cancer patient, since significant weight loss reduces the tolerance to anticancer drugs, reduces the functioning of the immune system, and is considered to be a major cause of death in the cancer patient.

In another study of 248 cancer patients, giving them Polyerga orally for 4 months improved appetite, reduced pain, increased energy and activity levels, and improved their general sense of well-being.[44] Furthermore, a reduction of the extent of the illness, along with a clear improvement of health, was recorded by observing physicians. Best results were obtained in breast cancer patients and patients experiencing colon and other carcinomas, whereas lung cancer patients and patients with metastases did not seem to respond as well to Polyerga.

Other studies have shown Polyerga to produce similar benefits, as well as enhance survival time and reduce metastasis (spreading) in patients with cancers of the colon, stomach, and lungs.[45] From the totality of existing clinical studies, animal studies, and test tube (in vitro) studies, it can be concluded that Polyerga does the following:

- Exerts significant immune-enhancing effects
- Prevents some side effects of chemotherapy, especially the detrimental effects on the immune system
- Enhances the effectiveness of conventional chemotherapy and radiation treatment
- Prevents metastasis
- Enhances the general sense of well-being, improves energy levels, and prevents detrimental weight loss in cancer patients
- Enhances both the quality of life and survival time in cancer patients

The Mechanism of Action

Many effects of Polyerga may be the result of boosting the output of γ-interferon.[46] This important chemical acts as the communication link between the macrophages and lymphocytes. Reduction in the level of γ-interferon results in significantly impaired immune function. Low γ-interferon levels are common in cancer patients. By increasing γ-interferon levels, Polyerga creates a cascading of effects that lead to enhanced immune function in cancer patients. Polyerga increases activation of natural killer cells.[47-50]

Other Uses

Polyerga may be helpful any time immune support is required, such as in chronic viral infections, including hepatitis C, human immunodeficiency virus (HIV), and Epstein-Barr syndrome. In a study of 10 patients with chronic hepatitis B, Polyerga administration (intramuscularly twice weekly and orally 3 tablets daily for 24 weeks) led to complete resolution in 3 of the 10 patients and lowering of liver enzymes in individuals with lower viral loads.[51] Polyerga may also be quite helpful to people who have had their spleens removed.

Dosage

Most studies with Polyerga used injectable preparations. Based on dose-effect studies in animals, as well as human clinical data, an effective oral dosage was determined. Each Polyerga tablet contains 100 mg of polypeptides. The optimum dosage recommendation is one to two tablets three times per day. For patients up to 140 lb body weight, the dosage is one tablet three times per day. For each additional 40 lb body weight, add a tablet (e.g., a 220-lb person would take five tablets daily in divided dosages). There is no toxicity with Polyerga, so there is no concern about overdosage.[52] However, taking more than recommended does not necessarily produce better results. For best results, Polyerga should be ingested on an empty stomach before meals.

Thymus Extracts

A substantial amount of clinical research supports the effectiveness of orally administered thymus extracts. Specifically, numerous clinical trials have shown that oral administration of predigested calf thymus extract, rich in thymus-derived polypeptides, is effective in doing the following:

- Preventing recurrent respiratory infections in children
- Correcting the T-cell defects in HIV infections (acquired immunodeficiency syndrome [AIDS])

- Treating acute hepatitis B infections
- Restoring the number of peripheral leukocytes in cancer patients with chemotherapy-induced depression of white blood cell counts
- Treating asthma, hay fever, and food allergies in children[53,54]

The effectiveness of the thymus extract in these conditions is reflective of broad-spectrum immune system enhancement presumably mediated by improved thymus gland activity. This effect fits in nicely with one of the basic concepts of glandular therapy (i.e., that the oral ingestion of glandular material of a certain animal gland strengthens the corresponding human gland). The result is a broad general effect indicative of improved glandular function. Interestingly, thymus extracts have been shown to normalize the ratio of T-helper cells to suppressor cells whether the ratio is low, as in AIDS, chronic infections, and cancer, or high, as in allergies, migraine headaches, and autoimmune diseases like rheumatoid arthritis.

Chronic Viral Infections

Recurrent or chronic infections, including chronic fatigue syndrome and chronic post-viral syndrome, are characterized by a depressed immune system. This is a difficult condition to treat due to the repetitive cycle of a compromised immune system leading to infection, which leads to damage to the immune system, further weakening resistance to viral infection. Thymus extracts may provide the answer to chronic infections by restoring healthy immune function.

The ability of thymus extracts to treat and then reduce the number of recurrent infections has been studied in groups of children with a history of recurrent respiratory tract infections. Controlled clinical studies revealed not only that orally administered thymus extracts were able to effectively eliminate infection, but also that treatment over the course of a year significantly reduced the number of respiratory infections and significantly improved numerous immune parameters.[55]

One of the most difficult viral infections for the body to eliminate is type B viral hepatitis. Thymus extracts have been shown to be effective in several clinical studies in both acute and chronic cases. In these studies, a therapeutic effect was noted by accelerated decreases of liver enzymes (transaminases), elimination of the virus, and a higher rate of seroconversion to anti-HBe, signifying clinical remission.[56,57]

The most extreme example of a chronic viral infection is AIDS. Although thymus extracts have not been shown to reverse this difficult disease, studies have shown an ability to improve several immune parameters, including an ability to raise the T-helper cells, a critical goal in AIDS treatment.[58]

Cancer

The primary application of thymus extracts in cancer has been to counteract the immune-suppressing effects of radiation and chemotherapy. The net effect of thymus extract administration is to prevent the tremendous depression of white blood cell levels and activity that result from chemotherapy or radiation.[54,59]

Allergies

In patients with allergies, levels of the allergic immunoglobulin-E antibody and eosinophils are typically elevated, whereas levels of suppressor T-cells are typically depressed. These abnormalities are clear indications of altered immune function.

The oral administration of thymus extracts has been shown in double-blind clinical studies to improve the symptoms and course of hay fever, allergic rhinitis, asthma, eczema, and food allergies.[54,60-62] Presumably this clinical improvement is the result of restoration of proper immune function, since levels of immunoglobulin-E and eosinophils have been shown to be reduced, whereas the ratio of helper to suppressor T-cells improved.

Interestingly, in several clinical studies, children receiving thymus extracts during food allergy elimination diets are often able to tolerate foods that had previously been allergenic and symptom producing.[61,62]

Autoimmune Disorders

Autoimmune disorders, such as rheumatoid arthritis, are characterized by autoimmunity. Central to this immune dysfunction is a high T-helper/suppressor cell ratio. A high T-helper/suppressor cell ratio results in increased antibody formation. The higher the ratio, the higher the number of antibodies being produced to damage body structures. In one clinical study, rheumatoid arthritis patients with a T-helper/suppressor cell ratio of 3.3 achieved normal ratios (1.02 to 2.46) after 3 months of therapy with a thymus extract.[54]

Although use of a thymus extract may not result in substantial clinical improvement, it appears to be useful in restoring proper immune function in autoimmune diseases, including rheumatoid arthritis, lupus, and scleroderma.

Dosage

From a practical view, products concentrated and standardized for polypeptide content are preferable to crude preparations. The daily dose should be equivalent to 120 mg pure polypeptides with molecular weights less than 10,000, or roughly 750 mg of the crude polypeptide fraction.

No side effects or adverse effects have been reported with the use of thymus preparations.

Thyroid Extracts

Desiccated natural thyroid is available by prescription according to USP guidelines. Preparations are derived from porcine thyroid glands. Many naturopathic physicians prefer natural thyroid to isolated synthetic T_4, since it contains both thyroxine (T_4) and tri-iodothyronine (T_3). Typical levels of thyroid hormone contained per grain in USP thyroid are 38 mcg of T_4 and 9 mcg of T_3.

The thyroid extracts sold as "nutritional supplements" are required by the FDA to be thyroxine free. However, it is nearly impossible to remove all the hormone from the gland. These nutritional thyroid preparations can be considered milder forms of desiccated natural thyroid.

The primary use of thyroid preparations is in the medical treatment of hypothyroidism. In all but its mildest forms, treatment involves the use of desiccated thyroid or synthetic thyroid hormone. For more discussion, see Chapter 177.

Dosage

Dosage is determined by clinical evaluation, including blood measurements of thyroid hormones (see Chapter 177 for directions).

SUMMARY

From the scientific data that currently exists, there is enough evidence to support the use of orally administered glandular extracts. For best results, physicians should choose glandular products made by reputable companies that employ established methods of manufacture to produce extracts of known concentration.

INTRODUCTION

Homeopathy is a highly systematized method of medical therapeutics and clinical evaluation. The term "homeopathy" is derived from the Greek words "homeos," meaning "similar," and "pathos," meaning "suffering." The medicines used in this system of therapeutics are chosen according to the Law of Similars (the concept of like curing like), a fundamental homeopathic principle based on the observed relationship between a medicine's ability to produce a specific constellation of signs and symptoms in a healthy individual and the same medicine's ability to cure a sick patient with similar signs and symptoms. This principle was first recognized by Hippocrates, who noticed that herbs given in low doses tended to cure the same symptoms they produced when given in toxic doses.

Homeopathic medicines are derived from a wide variety of plant, mineral, and chemical substances. They are prepared according to standards of the U.S. Homeopathic Pharmacopoeia, a revised version of which has been approved by the U.S. Food and Drug Administration and U.S. Congress.

HISTORY

The homeopathic school of medicine was founded by a German physician, Samuel Hahnemann. He had already gained a reputation in chemistry and medicine, having formulated a soluble form of mercury and developed a safer method for its use, and having written a number of works on pharmacology, hygiene and public health, industrial toxicology, and psychiatry. His treatise on arsenic poisoning (1786) is still considered authoritative. A prolific writer, Hahnemann collected, compiled, revised, and edited the existing pharmacologic knowledge. The work was well received by the medical profession of the time. Hahnemann was one of the most learned men of his generation in medicine, chemistry, and pharmacology, making his later criticisms of medicine all the more significant.[1]

Disillusioned with the theories and practice of eighteenth century medicine, Hahnemann retired from practice in 1782 and spent the next 14 years earning a meager living doing chemical research; writing; and translating English, French, Italian, and Latin works. He wrote of his time of practice:

> *It was painful for me to grope in the dark, guided only by books in the treatment of the sick. To prescribe according to this or that (fanciful) view of the nature of diseases, substances that only owed to mere opinion their place in the materia medica; I had conscientious scruples about treating unknown morbid states in my suffering fellow creatures with these unknown medicines which, being powerful substances, may, if they were not* exactly *suitable (and how could the physician know whether they were suitable or not, seeing that their peculiar special actions were not yet elucidated) easily change life into death, or produce new affections and chronic ailments, which are often more difficult to remove than the original disease.*

In his struggle to determine a reliable basis for therapeutics, he was distressed by his inability to provide medical care for the acute illnesses of even his own growing family. In 1790, during his translation of William Cullen's (a Scottish physician) *Materia Medica*, he added a footnote disagreeing with Cullen's conclusions that the basis of cinchona bark's effectiveness was its bitter and astringent qualities. *Cinchona officinalis* (peruvian bark), from which the drug quinine is derived, was known to be clinically effective in malaria and intermittent fevers (then called ague). He argued that there

were several drugs in common usage that, in smaller doses, had greater bitter and astringent qualities yet had no specific action on fevers. As an experiment, Hahnemann took four drachms of cinchona twice daily and soon developed the paroxysmal symptoms characteristic of intermittent fevers.

This duplication of symptoms was a revelation to him and ultimately resulted in his formulation of the concept of determining the properties of a medicine by studying its effects on healthy humans.

Although homeopathy offers a profoundly deep and unified evaluation in the treatment of chronic diseases (see the section on "Follow-Up and Case Evaluation"), it had gained most of its early reputation in the treatment of acute and epidemic diseases. An uproar was caused in Cincinnati in 1849, when two immigrant German homeopaths, treating cholera with camphor and other homeopathically prescribed remedies, published statistics in newspapers indicating that only 35 of their 1116 treated cases had died. During the nineteenth century, 33% to 50% of patients with cholera who were given standard medical care died. In the 1879 epidemic of yellow fever, New Orleans homeopaths treated 1945 cases with a mortality rate of 5.6%, whereas standard medical doctors were losing 16% of patients. These and similar statistics had a profound effect on Congress and public opinion.[2]

Over time, homeopaths established their own network of treatment facilities. By 1892, in the United States, they controlled 110 hospitals, 145 dispensaries, 62 orphan asylums and retirement homes, more than 30 nursing homes and sanatoria, and 16 insane asylums.

Constantine Hering established the first homeopathic medical school in the United States in 1835. It later moved from its original site in Allentown, Pennsylvania, to Philadelphia, where it remains today as an orthodox medical school: the Hahnemann Medical College and Hospital. Hering's promotion of homeopathy and development of the materia medica was equaled only by Hahnemann himself. His 10-volume work, *The Guiding Symptoms of Our Materia Medica*, remains a definitive work on the clinical verifications of the homeopathic approach. Unfortunately, of the many medicines introduced by Hering, only nitroglycerine remains in orthodox medical practice as a tribute to his medical genius.

Throughout the world, homeopathy has maintained a consistent tradition. Frederick Harvey Foster Quinn introduced it to England in the 1840s. It has since become a postgraduate medical specialty, recognized by the Department of Health by virtue of an Act of Parliament. Homeopathic hospitals and outpatient clinics are part of England's national health system. Homeopaths have been engaged as personal physicians to the Royal family for the past four generations.

Homeopathy is widely practiced in Europe, India, Argentina, and Mexico, and is experiencing a renaissance in the United States.

PHILOSOPHY

Provings

Hahnemann defined his method of testing medicines on healthy people as "provings." He expanded his investigations to include a wide range of substances, using his family, friends, and associates as experimental subjects.

Historically, Hahnemann was not the first to use this methodology. In 1760, Anton Stoerck reported testing *stramonium* (datura) by rubbing it on the skin, inhaling the vapors of the freshly crushed leaves, and, finally, ingesting the fresh extract. He theorized that if *stramonium* disturbs the senses and produces mental derangements in healthy people, it might be administered to maniacs for the purpose of restoring the senses by effecting a change of ideas.

Medical literature contains examples of inadvertent provings: in 1983 a study in the *New England Journal of Medicine* reported that pyridoxine (vitamin B_6), which is used in the treatment of some types of peripheral neuropathy, was also capable of producing neuropathies when given in large doses.[3] In 1796, Hahnemann published, in *Hufeland's Journal*, the fruit of his investigations in an article, "Essay on a New Principle for Ascertaining the Curative Power of Drugs, with a Few Glances at Those Hitherto Employed."

Like Treating Like

Hahnemann also recognized the tendency of a natural disease to have a "homeopathic effect" (i.e., a preventive or therapeutic effect) on other diseases with similar symptomatology. Although he ascribed this to the stimulation of the organism to eradicate the disease, he felt the deliberate induction of a disease to be difficult, uncertain, and dangerous.[4] This concept has many parallels in modern medical science. Descriptions of viral interference under natural conditions were described in 1937 by G. Findlely and F. MacCallum, who found that monkeys infected with the Raft Valley fever virus were protected from the more fatal yellow fever virus. They adopted the term "virus interference" and believed that when one virus infects a group of cells, a second virus is somehow excluded.[5] This eventually led to the discovery of interferon in 1957 by Alick Isaacs and Jean Lindenmann. These methods of inducing self-regulation are critical in enhancing the ability for the body to recognize and resolve illness.

In 1799, Hahnemann gained increased professional acceptance of his ideas by the successful application of *atropa belladonna* (deadly nightshade) in the prevention and treatment of scarlet fever (which had at that time reached epidemic proportions). In 1860, it was recommended as the treatment of choice in the National Dispensatory, which stated: "As long as persons are under the influence of belladonna the liability to contract scarlatina is very much diminished."[6]

The Organon of Medicine

In 1810, Hahnemann published his *Organon of Medicine*, a book that, through six editions, formed the foundation and definition of the homeopathic practice of medicine. It contains the philosophy, observations, and clinical applications of homeopathy, as well as citations from the historical and current literature of the time. Hahnemann challenged the reductionistic and mechanistic practices of his time, stating that the nature of disease is dynamic and could not be defined by isolating processes, grasping for an explanation. He further asserted that the cause of disease could not be known and that the categorization of disease states and attempts to manipulate physiology were insufficient, because they did not address the integrity and complexity of organization of the organism as a whole.

He described this organization as dynamic, meaning in accordance with the animating principle of life, which is the underlying energetic pattern to which matter conforms.

Disease is therefore addressed descriptively in the context of the whole patient, with the patient's unique symptoms being indicative of that individual's vital response to the condition. For any given disease there may be a long list of remedies that have been clinically effective, but it is the individualization and differentiation among medicines, based on the patient's unique indications, that leads to a successful homeopathic prescription.

Vitalism

Disease, in the homeopathic model, is thought to arise from inherent or developed weaknesses in the patient's defense mechanisms, creating a susceptibility to "morbific influences" (e.g., toxic factors in the environment, bacteria, psychological stresses). This viewpoint is considered "vitalistic" (see Chapter 3, Hierarchy of Healing, and Chapter 5, Philosophy of Naturopathic Medicine, for further discussion) and, although it does not deny a corporeal reality, considers pathology to be but a singular focus in a complex net of interactions.

William Boyd, in *A Textbook of Pathology*, discussed the limitations of the causal approach to disease currently in vogue in medicine when he stated[7]:

> *We must admit, however unwillingly, that we seldom or never really know the cause of anything. Many a beautiful idea has been slain by ugly fact. We merely note a constant association with one thing always following another. We say that the tubercle bacillus is the cause of tuberculosis. That is merely another way of saying that the bacillus is associated with a constant type of lesion; it is no explanation of how the lesions are produced by the bacillus. Nor does it explain why some persons and animals are susceptible to the infection while others are immune.*

Vitalism can be better understood in the context of Hahnemann's time, when theories of the causation of disease and its treatment abounded, such as Galen's doctrine that the secondary quality of a medicine (i.e., its action on the disease) could be determined from its primary qualities, such as its taste or smell; the evaluation of medicines by the study of their interactions when mixed with human blood in a jar; iatrochemistry, which had been reduced from the Paracelsian application of spagyric tinctures or oils of metals to dangerous toxic doses; the classification of drugs according to the Dioscoridian approach, which was based on the physiologic action (e.g., diuresis, diaphoresis) and chemical composition; and the "doctrine of signatures," which held that the outer form and color of a plant revealed its inner archetypal action.[8,9]

Although some studies of the effects of medicinal agents were done with animals, Hahnemann observed that they had different effects on humans; pigs could safely eat *nux vomica* in quantities that would immediately kill humans. Dogs could eat *aconitum napellus*, a deadly poison to humans, without injury. He also rejected the method of testing drugs by studying their effects on the sick as haphazard and unreliable, particularly because the results being sought were often only symptomatic relief rather than eradication of the disease state.

Hahnemann defined the application of medicines whose purpose was to alter physiology or act as an antagonist to disease as the practice of "allopathy" ("allo," meaning "contrary" in Greek). The current dominant medical system is heavily influenced by the causalistic and allopathic paradigms. This results in the diagnosis being the focal point of practice, without which appropriate therapy cannot be instituted. The pharmacologic approach is limited to the end results of disease rather than the origins of pathogenesis. Subsequent problems are classified as unwanted side effects, because only the primary action of the pharmaceutic agent is used for treating a specific disease state. By focusing on only the primary effects of a drug, a diverse remaining range of physiologic, as well as psychological effects, are ignored.

In the homeopathic model, the side effects are an important part of the agent's action and the body's response to them, and by ignoring them, a drug's range of usefulness is greatly limited, whereas its toxicity is increased. Hahnemann's empiric investigations not only led to new applications of medicines but provided a method for integrating the physical, mental, and emotional effects of a drug. This allowed the treatment of the totality of a patient's symptoms as a dynamic pattern of interaction.

Vitalists stress the teleologic behavior of organisms (i.e., the goal directedness and design in biological phenomena). Disease is therefore regarded as a positive expression of the organism's self-regulatory process in response to environmental or other stresses. Disease is not accidental but is rather the effort of the organism to ward off deeper or more internal disorganization. It is the natural wisdom of the body, the *vis medicatrix naturae*, or, using current scientific terminology, the tendency of the body to maintain homeostasis. Medical intervention often acts in conflict with these vital intracellular and extracellular regulatory functions.

Karl Menninger, in 1948, commented on this medical dilemma[10]:

> *I believe that clinicians have come to think more and more in terms of a disturbance in the total economics of the personality, a temporary overwhelming of the efforts of the organism to maintain a continuous internal and external adaptation to continuously changing relationships, threats, pressures, instinctive needs and reality demands … It is the imbalance, the organismic disequilibrium, which is the real pathology, and when that imbalance reaches a degree or duration that threatens the comfort or survival of the individual, it may correctly be denoted disease.*

Homeopathy is a method of specific induction of nonspecific resistance that stimulates the body's inherent defense and self-regulatory mechanisms, rather than by taking over a function of the body, initiating dependency on the medicine itself.

THE CLINICAL APPLICATION OF HOMEOPATHIC PRINCIPLES

The homeopathic clinical and therapeutic process consists of three interrelated processes: case taking, evaluation, and prescribing. The process is comprehensive and engages the observations of the patient, as well as those of the doctor. Hahnemann described the process in paragraphs 84 to 103 of the *Organon* and stressed the importance of distinguishing between chronic and acute, or self-limiting, disease.

The Homeopathic Interview

The initial history of complaints is elicited from the patient with as little interruption as possible (as long as the patient does not digress unduly), so that the patient's train of thought is not disrupted or directed along lines imposed by the physician's biases. According to Hahnemann:

> *The physician elicits further particulars about each of the patient's statements without ever putting words in his mouth, or asking a question that can be answered only by yes or no, which induces the patient to affirm something untrue or half true or else deny something really there to avoid discomfort or out of desire to please, thereby giving a wrong picture of the disease, which would lead to the wrong treatment.*

An entire review of symptoms is recorded in descriptive detail, taking into consideration all modalities that affect a symptom. Hahnemann emphasized the general symptoms (i.e., those affecting the entire organism), as the leading indications for the remedy. These key symptoms include mental and emotional affects, the

metabolism and its reactions to environmental stimuli, sleep positions, food cravings and aversions, thirst, body type, and all manifestations of unconscious and autonomic regulation.

Unique characteristic symptoms, particularly those regarded as "strange, rare, and peculiar," are important considerations in the selection of the remedy. These might be the expression of a paradoxic or unusual relationship, such as pain ameliorated by pressure or the sensation of the legs being made of wood or glass. The association of the start of a disease or symptom complex with an environmental or emotional event can be key and emphasizes the importance of an accurate and extensive interview.

Hahnemann emphasized the importance of taking a comprehensive case, particularly in chronic disease[11]:

> *In chronic diseases in women one should pay particular attention to such things as pregnancy, infertility, sexual desire, confinement, miscarriages, nursing, vaginal discharges, and the condition of the monthly flow, especially noting whether it recurs at intervals that are too short or too long, how many days it lasts, whether or not it is interrupted, the quantity, how dark with color, any leukorrhea before or after the flow. If there is leukorrhea, what it is like, what symptoms accompany it, what is its quantity, under what conditions does it appear, what brings it on?*

Because the patient's symptoms are the expressions of the body's attempts to heal itself, symptomatic treatment (i.e., many allopathic therapies) can impair the physician's ability to obtain vital information and complicate the taking of the case. This problem has also been recognized by some medical authors, such as Boyd, who stated: "We recognize that the pattern of disease has changed out of recognition during the last 30 to 40 years owing to modern drugs, particularly the antibiotics."[7]

Follow-Up and Case Evaluation

Considering the vitalistic and holistic perspective of the homeopathic approach, a clear definition of cure is necessary to establish the treatment goal. Mere palliation or suppression of symptoms at the cost of the overall vitality and function of the individual is considered negligent by the homeopathic practitioner. For example, if a patient's skin disease is treated and appears to resolve but is followed by asthma, fatigue, and confusion, the treatment is evaluated as having been suppressive. If, upon proper treatment, the more serious lung and systemic disruptions are alleviated and the previous skin lesions return, the patient is considered as progressing toward a cure. When further appropriate therapy results in final alleviation of the skin disease, without any undue stress to the patient, it is then considered a true cure.

This evaluative procedure is part of Hering's Law of Cure, an observation of the principles of curative responses that can be applied to any healing process, regardless of the school of thought. In true healing, according to this set of observations, symptoms follow these patterns:

- From above, down the body to the extremities
- From within to without (often in the form of discharges and other eliminative processes)
- From the most important organs (e.g., the central nervous system) to the least important organs (typically, the skin)
- In reverse order of their appearance (i.e., the chronologically most recent being replaced by those of the earlier stages of the disease, and, in some instances, earlier in the patient's life)

Homeopathy holds that the disease first affects the vital force and is manifested first by a change in the patient's well-being, long before any objective changes can be observed. Illness is usually first recognized when the patient becomes aware of the early manifestations of the disease.

Disease and cure must also be considered in the context of the belief system and culture of the patient. Much of what we call disease arises from the individual's inability to find meaning and purpose. Many forms of healing are capable of enabling the person to integrate into the fabric of daily life and of providing ways to help the person address personal needs for fulfillment.

In his study of disease, Hahnemann noted that there were inherited predispositions to disease, which he related to the improper treatment, and therefore suppression, of skin eruptions and venereal disease. He called these predispositions miasmas and, in 1828, published his findings in *Chronic Diseases: Their Nature and Homeopathic Cure*. He observed that many people, despite apparently healthy lifestyles, develop degenerative diseases. These often become established in childhood and continue to plague the person throughout life, despite medical treatment. He described three miasmas: psora, which represents a fundamental flaw in human ability to eradicate disease related to the suppression of skin disease; syphilis; and sycosis, which is caused by the suppression of the figwort, or what is now known as human papilloma virus. Hahnemann described the chronic effects of bacterial and viral diseases in his explanation of miasmas. In his discussion of viral diseases such as smallpox and other epidemic diseases, Hahnemann's descriptions of the nature of viruses and their treatment predate their discovery by 50 years. He was a contemporary of Edward Jenner and supported his use of smallpox vaccination.

More recently, George Vithoulkas, a contemporary homeopathic author and teacher, defined health on three levels: mental, emotional, and physical. The mind should be capable of functioning with clarity, rationality, coherence, and logical sequence. It should be capable of engaging in creative service for the good of others, as well as for the good of oneself, demonstrating a freedom from selfishness and possessiveness. On the emotional level, there should be a state of serenity free from excessive passion, a state that should not be confused with lack of emotional response generated as a protection against emotional vulnerability. Finally, on the physical level, there should be freedom from pain. The healing person should experience a subjective sense of well-being and a progressive increase in vitality.[12]

Prescription

Because homeopathy is oriented toward the administration of a single medicine at a time, careful prescribing is important. It is through the application of single medicines that homeopathic physicians have been able to record clinical verification of the provings and amass an impressive body of literature.

Combination homeopathic medicines have been introduced as specific remedies for diseases and therefore have not represented homeopathic methods, although many studies support their efficacy.

The process of selecting the correct remedy involves both careful study of the patient's symptomatology and medical history and matching these with the appropriate remedy. This requires a sound understanding of the homeopathic materia medica (see section on "The Study of the *Materia Medica*").

The symptoms of the homeopathic materia medica are indexed in repertories that have evolved both in reference books and computer analysis programs.

Homeopathic Pharmacy and Potency Selection

This leads to a discussion of what has remained the greatest mystery of homeopathic medicine (and the source of considerable ridicule and misunderstanding): the use of "potentized" substances.

As Hahnemann began his research, he found that when treating patients according to the Law of Similars there was an initial aggravation of the symptoms, the "healing crisis," when using the high dosages typical of that era. He empirically tried using progressive dilutions of the medicines, beginning with tinctures from plants and triturations with milk sugar for metals and salts. He made the dilutions serially by mixing 1 drop of the tincture to 100 drops of alcohol, which were then "succussed" (shaken by pounding against a resilient surface) vigorously. He found that, with increasing dilution, the severity of the aggravation lessened while the patient continued to improve, often with deeper and more enduring results. He called these diluted remedies "potentized." As an analytic chemist, he was aware of Avogadro's theories (they were contemporaries), but he persisted in evaluating dilutions beyond the point where chemical activity could be detected.

This challenge to the present understanding of therapeutic mechanism has been addressed by recent workers, who have suggested that the therapeutic properties of the remedy lie in the energetic impression they make on the diluting vehicle (typically alcohol and water or lactose). Various techniques have been used to determine if there is a physical difference between the potentized dilution and the unmodified vehicle. These studies have used ultraviolet spectroscopy, conductivity measurements, infrared spectroscopy, surface tension measurements, Ranian-Laser spectroscopy, nuclear magnetic resonance, and other methods. Much of this work has shown regular peaks and troughs in activity with progressive dilutions, and Heintz claimed that the peaks corresponded to the maximum effects found in the biological studies he reported (see section on "Basic Research").[13]

Mechanism of Action

To date there is no conclusive understanding of the mechanism of action of the potentizing process. However, this has not inhibited the use of potencies, which have been diluted by a factor of 100 up to 100,000 times ($10^{200,000}$). At this time, most explanations for the mechanism of homeopathic high potencies are provisional (such as the postulate that the remedies act in resonance with the magnetic fields of the body, or that the physiochemical properties of water can be modified by a solute and remain so even in the absence of the solute).[14]

This has not affected clinical practice or demonstration of efficacy in clinical trials any more than the use of aspirin did, despite the fact that the discovery of its mechanism of action through modulation of prostaglandins did not occur until the 1980s. There are many forces whose nature can only be recognized by their results (e.g., gravity). These observations of relationships, confirmations of experience, are the basis of an empiric system. Medicine remains an art in the field of science.

Interestingly, a group operating in the Hematology Department of the School of Pharmacy in Bordeaux, France, tested both the effect of common aspirin and homeopathic preparations on the vascular walls of rats. Aspirin at high concentrations (100 mg/kg) induced a decrease in platelet aggregation (amplitude and speed), as well as a decrease in the area of the thrombi (arterial and venous) and the number of emboli (arterials and venous).

Aspirin at ultra-low doses (9, 15, 30 CH) induced an increase in platelet aggregation (amplitude and speed), as well as an increase in the area of thrombi (arterial and venous) and the number of emboli (arterial and venous). The antiaggregation and antithrombotic action of aspirin at high concentrations (100 mg/kg) was inhibited by the concomitant injection of aspirin 15 CH.[15]

This confirmed Hahnemann's observations of the primary and secondary effects of medicines mentioned in the *Organon.*[16] Bellavite described these effects as "biologically active compounds (which) may cause inverse or paradoxical effects on a complex homeostatic system when either the doses of the compound, or the methods of preparation and of administering, or the sensitivity of the target system are changed."[17,18]

Research into both the pharmacologic effects of homeopathic preparations and the paradoxic effects of orthodox drugs that confirm the Law of Similars' underlying homeopathic prescribing are a growing body of literature. Certain pharmacologic substances when tested in high dilutions act on the same biological systems.[19-25]

The reaction to the high dilutions can also be the opposite to a drug at low dilutions (e.g., proinflammatory agents can be anti-inflammatory at high dilutions).[26-29]

Paradoxic effects of medicines are the basis of the Arndt-Schulz Law in pharmacology and hormesis. The Arndt-Schulz law states that weak stimuli slightly accelerate vital activity, medium strong stimuli raise it, strong ones suppress it, and strong ones arrest it.[30]

Southam and Erlich[31] reported the stimulatory effect of an antifungal agent when used at low doses and proposed the term "hormesis." Hormesis is defined as "the stimulatory effect of subinhibitory concentrations of any toxic substance on any organism."[32] Hormesis is considered a nonspecific phenomenon that increases the resistance and growth of the treated organism. It exists in all living organisms. This "action–reaction" model shows the efficacy of the "vital activity" in fighting the poison in a nonspecific way, although specific defense molecules are also synthetized.[33-38] A modern and important pathologic model showed that a single dose of an antitumoral immunosuppressive substance (cisplatin) induced increased lymphokine-activated killer activity.[39] Wagner and colleagues demonstrated that low doses of cytostatic agents stimulated human granulocyte and lymphocyte growth.[40]

The goals and methods of homeopathic pharmacy have their roots in earlier Paracelsian and spagyric medical systems. The challenge remains to define homeopathic empiric science in the context of a modern science. It may be that homeopathy presents a challenge to science itself that will bring forth new models for pharmacology. The more central challenge is for homeopathy to discover how it can apply its own critical methods to develop a more effective health care service.

The assumption that we can find substances in nature that can alter disease underlies the history of medicine and pharmacology, yet healing remains a mystery. Further studies are necessary to confirm and develop the understanding of the mechanisms and validity of homeopathic medicines.

Determination of Potency

In terms of clinical practice, general guidelines have evolved for the determination of potency. In the sixth edition of the *Organon*, Hahnemann recommended ascending the scale of potencies gradually. In paragraph 248, he suggested that the medicinal solution be "succussed anew with use." In chronic cases, the patient is directed to take one teaspoonful daily or every other day, and in acute diseases, as frequently as needed. If the solution is used up before the problem alleviates, the next higher dilution is used (if still indicated by the symptom pattern).[41]

The higher potencies, whose use largely developed in the United States, are repeated much less frequently and are generally reserved for the experienced practitioner. The more potentized the remedy, the closer it must meet the Law of Similars (i.e., the accuracy of the prescription must be high for a curative effect). Lower potencies are often repeated daily, depending on the condition being treated.

Several ranges of potencies include the decimal scale, which uses a 1:10 dilution; the centesimal scale, which is diluted 1:100; and the LM potencies introduced in the sixth edition of the *Organon*, using daily doses of 1:50,000 dilutions.

It is important to note that the sixth edition was unavailable until 1924, 76 years after Hahnemann's death. The predominant clinical application of homeopathic potencies had developed using an ascending scale. A single dose was used until its action had ceased, when the same potency would be repeated. When that potency seemed to no longer demonstrate an enduring effect, a higher potency was used. There have been regular arguments between low- and high-potency prescribers as to the most effective method.

The Study of the *Materia Medica*

Constantine Hering once stated the following:

> *A mere acquaintance with the principal symptoms cannot be called studying the* materia medica, *although we make it the basis of our study. The study of* materia medica *must be regarded and dealt with in exactly the same manner as that of other natural sciences.*

To give a perspective on the way in which homeopathic physicians organize the proving symptoms into clinical pictures, we draw from an essay on *Sepia* by E.B. Nash[42]:

> *This is another of our wonderful remedies of which the dominant school knows nothing, except what they have learned from us. Its chief sphere of action seems to be in the abdomen and pelvis, especially in women. No remedy produces stronger symptoms here. We quote from different but equally good observers.*
>
> *Sensation of bearing down in the pelvic region, with dragging pains from the sacrum; or feeling of bearing down of all pelvic organs. (Hahnemann)*
>
> *Labor-like pains accompanied with the feeling as though she must cross her legs and "sit close" to keep something from coming out through the vagina. (Guernsey)*
>
> *Pain in uterus, bearing down, comes from back to abdomen, causing oppression of breathing; crosses limbs to prevent protrusion of parts. (Hering)*
>
> *Prolapse of the uterus, of the vagina, with pressure as if everything would protrude. (Lippe)*
>
> *Experience has shown its value in cases of ulceration and congestion of the os and cervix uteri. Its use supersedes all local applications. (Dunham)*
>
> *No higher authority than the united testimony of these five of our best observers could be brought to show the action of* Sepia *upon the pelvic organs.*
>
> *Now when we come to examine the provings in Allen's* Encyclopedia*, we find that these symptoms were mainly produced by Hahnemann and his provers, and Hahnemann advocated proving remedies in the 30th, and some of them were produced by the 200th, especially those most strongly verified by black-faced type.*
>
> *We confess that we cannot understand how so many question the value of potencies for proving or curing* Sepia*, like* Sulphur*, affects the general circulation in a very marked manner. Flashes of heat with perspiration and faintness is almost as characteristic of this remedy as of* Sulphur*. But there are, with* Sepia*, more apt to be associated with them the pelvic symptoms already given, and they are also more apt to occur in conjunction with the climacteric. Indeed, these flashes often seem with* Sepia *to start in the pelvic organs and from thence to spread over the body.*
>
> *But this irregularity of circulation extends as far as that of* Sulphur*. The hands and feet are hot alternately, that is, if the feet are hot, the hands are cold, and* vice versa*. There is not so much sensation of burning with* Sepia *as with* Sulphur*, but there is actual heat, and the venous congestion, which seems to be the real state of the organs where the pressive bearing down et cetera is felt, is also accompanied with much throbbing and beating.*
>
> *This local congestion to the pelvic organs is not simply sensational. There are actual displacements in consequence of it, and the long continued congestion results in inflammations, ulcerations, leukorrheas and even malignancies or cancerous organizations. Induration with a painful* **sense** *of stiffness in the uterine region is characteristic.*
>
> *This pelvic congestion also affects the rectum in a marked degree. The rectum prolapses, there is a sensation of fullness, or of a foreign substance as of a ball or weight, and oozing of moisture from the rectum. Indeed, the rectal and anal symptoms are almost as strong as the uterine and vaginal. It is impossible to enumerate all the symptoms connected with the circulatory disturbances of* Sepia *in such a work as this, only a general study of the Materia Medica can do it.*
>
> *The urinary organs come in for their share of symptoms. The same pressure and fullness consequent upon the portal congestion reaches here. We will now proceed to give what we have found to be particularly valuable symptoms under the various organs in this region. "Pressure on bladder and frequent micturation with tension in lower abdomen." "Sediment in the urine like clay; as if clay burnt on the bottom of the vessel; urine very offensive* (Indium)*, can't endure to have it in the room, it is reddish or may be bloody." This is found mostly in women. With children there is one peculiar symptom which has often been verified. "The child always wets the bed during its first sleep."*
>
> *Upon the male organs I have found it particularly useful in chronic infection. There is not much discharge, but a few drops, perhaps, which glue up the orifice of the urethra in the morning; but it is so persistent and the usual remedies will not "dry it up." In my early practice I used to use a weak injection of* Sulphate of Zinc*, but it used to annoy me that I could not use it without resorting to local measures.* Sepia *does it in the majority of cases and* Kali iodatum *will do it in the rest. I have, where there was a thick discharge of long standing and the smarting and burning on urination continued, several times finished the case with* Capsicum.
>
> *As a rule, this long continued slight, passive gleety discharge is a result of weakness of the male genitals,* as is shown by a flaccidity of the organs and frequent seminal emissions. The emissions are thin and watery. Sepia *covers all of this and often sets all to rights in a short time.*
>
> *The mind symptoms of* Sepia *are like* Pulsatilla*, in that she is sad and cries frequently without knowing the reason why. So if in a tearful mind with uterine disturbances* Pulsatilla *should fail*

you, the next remedy to be studied is Sepia*. But there is another condition of mind not found under* Pulsatilla *or any other remedy in the same degree, and that is, that, notwithstanding there is no sign of dementia from actual brain lesion, the patient, contrary to her usual habit, becomes indifferent to her occupation, her house work, her family or their comfort, even to those whom she loves the best. This is a very peculiar symptom and a genuine keynote for the exhibition of* Sepia…

I once cured a very obstinate case of entero-colitis (so-called cholera infantum), after the complete failure of two eminent allopaths, with Sepia*, the leading symptom being, always worse after taking milk. Oozing of moisture from the anus finds its remedy here sometimes, but oftener in* Antimonium crudum*. The* Sepia *patient is very weak. A short walk fatigues her very much. She faints easily from extremes of cold and eat, after getting wet, from riding in a carriage, while kneeling at church, and on other trifling occasions. This fainting, or sense of sinking faintness, may be found in pregnancy, child bed, or during lactation; or, again, it may come on after hard work, such as "laundry work;" so it has come to be called the "washer woman's" remedy.*

As can be seen by this excerpt, the indications for a remedy are complex, requiring study and understanding.

RESEARCH IN HOMEOPATHY

Homeopathy arose from empiric observations and operates from empiric clinical evidence and phenomenologically descriptive fields. Samuel Hahnemann was the first to use the methodology of provings, to gather information about the reactions of healthy subjects to the ingestion of minute amounts of substances. Both clinical trials and laboratory research, although relatively sparse and often inconclusive, do point to efficacy and activity beyond placebo. Homeopathy has faced challenges in the scientific as well as political arena, because its mechanism of action is still unknown. For example, quoting from a recent review, "…according to current pharmacological theory it would appear impossible that homeopathic therapy could have any effect over placebo." [43] However, as the authors go on to say, "The available hypotheses for a possible mechanism of action, however, do not claim that homeopathic remedies act through pharmacological but through biophysical pathways and all include the idea of some form of information transfer…."[43] Despite adversaries who claim that research has determined that homeopathy is nothing more than placebo, homeopathy researchers, utilizing increasingly sophisticated research designs, continue to produce intriguing evidence regarding the effects and efficacy of homeopathic substances. This evidence, which emerged from several types of research, including provings, clinical trials, and laboratory studies, may soon converge to build a promising case for homeopathy's impact.

Evidence from a Modern Proving Study

Although traditionally provings, also called pathogenetic trials, first involved material doses of substances, Hahnemann himself, as well as later provers, conducted proving studies using potencies beyond Avogadro's number. One recent proving study provided convincing evidence that ultramolecular doses of homeopathic substances can produce symptoms different from placebo.[44] This double-blind, placebo-controlled experimental study randomized 25 medical doctors into three groups who received 30 CH potentized doses of either *Natrum muriaticum* or *Arsenicum album*, or an identical placebo. All substances were beyond Avogadro's number in terms of dilution. The main outcome parameter was number of remedy-specific symptoms per group. The actual remedies themselves were chosen randomly from a list of 20 already proven remedies that are frequently used in homeopathic practice; this list was not known to subjects or the study team, other than the study director and pharmacist; the two selected remedies were not known to anyone on the study team, including the study director. Participants were advised to ingest five remedy globules on day one, then 2 × 5 on day two, or until symptoms appeared, and then write their symptoms in a diary over 4 days. These symptoms were compiled and reviewed by an independent homeopathic expert, blinded to group assignment, who analyzed each symptom via a computer program for its typicality, or not, for one of the two remedies tested. The results showed that symptoms typical for the respective remedy were significantly more likely to occur in both the *Natrum muriaticum* or *Arsenicum album* groups, whereas nonspecific symptoms were more frequent in the placebo group ($P = 0.001$). Typical symptoms reported by subjects ingesting *Arsenicum album* included "strange restlessness"; "increased desire to swallow"; "lack of desire to urinate"; and "gushing diarrhea." Typical symptoms reported by subjects ingesting *Natrum muriaticum* were "difficulty concentrating"; "slight vertigo when seated"; "tearing pain in scalp"; "twitching in right eye"; and "cramping like labor in abdomen."[44] This impressive finding showed that nonmaterial doses of substances produced specific and distinctive effects—characteristic of the remedy—in subjects who were blinded to which remedy they were ingesting.

Human Clinical Trials

Although the above study provides evidence for an effect of ultramolecular homepathic substances on the human organism, what is of primary interest to humans, and particularly clinicians, is whether such effects are therapeutic. In one early classic study, Gibson et al[45] published a double-blind clinical trial of homeopathic treatment in rheumatoid arthritis. The 3-month study was elegantly designed in that the prescribing was individualized to the patient's symptoms and was controlled, on a double-blind basis, by giving half the patients the correct remedy and the rest a placebo. All patients continued to use conventional, nonsteroidal, anti-inflammatory drugs, and the treated group showed significant improvement in subjective pain, articular index, stiffness, and grip strength. Other published studies demonstrated the efficacy of homeopathic treatment for treatment of headache, bruising, cancer-related symptoms, attention-deficit-hyperactivity disorder in children, asthma, upper respiratory tract infections, otitis media, arthritis, allergies, male infertility, influenza, cardiac insufficiency, herpes, osteoarthritis, acquired immunodeficiency syndrome, and chronic fatigue syndrome.[46-83]

Meta-Analyses and Systematic Reviews of Human Clinical Trials

Hundreds of human clinical trials, of varying quality, with both positive and negative results, have now been carried out. Meta-analyses and systematic reviews have been helpful in identifying promising treatments and areas where more research is needed, thus moving the field forward.

In 1991, a meta-analysis by Kleijnen et al[84] was published in the *British Medical Journal* of a total of 105 controlled trials. The quality of trials was described as poor for two thirds of those reviewed. Positive results for homeopathic treatment were found in 81 trials, leading the authors to state, "The evidence in this review would

probably be sufficient for establishing homeopathy as a regular treatment for certain indications."

In 1997, Linde et al[85] published another meta-analysis of 119 trials that met the inclusion criteria; 89 had adequate data for meta-analysis, and 2 sets of trials were used to assess reproducibility. The combined odds ratio for the 89 studies was 2.45 in favor of homeopathy, with an odds ratio of 1.78 for the 26 good quality studies. The authors concluded, "The results of our metaanalysis are not compatible with the hypothesis that the clinical effects of homeopathy are completely due to placebo."

Accumulating evidence is beginning to make it feasible to carry out systematic reviews to evaluate homeopathy's use for treatment for specific conditions. For example, in a review of homeopathic treatment of people with human immunodeficiency virus or acquired immune deficiency syndrome, five controlled clinical trials were identified, with evidence for improved CD4 and CD8 counts, and specific physical, immunologic, neurologic, metabolic, and quality-of-life benefits. The author concluded that homeopathy might play a useful role as an adjunctive therapy in this condition.[82] Pilkington et al[83] examined the use of homeopathy for anxiety and anxiety disorders, concluding that homeopathy might be beneficial. One particularly fruitful and positive research, for which there are several positive trials, is in the use of homeopathy for treatment of respiratory allergies.[75]

Human Effectiveness Studies

Effectiveness research involves evaluation of a treatment's usefulness in more natural or real-world settings. For example, during World War II, isopathic preparations were given prophylactically, and homeopathic therapies were used in mustard gas burns. A subsequent statistical analysis found that these treatments yielded significant results compared with placebos. The remedies used were mustard gas, *Rhus toxicodendron*, and kali bichromium.[13]

More recently, Witt et al[86] evaluated health status changes of chronically ill patients after 8 years of homeopathic treatment. This prospective, multicenter cohort study involved 103 homeopathic primary care practices in Germany and Switzerland; a total of 3709 patients were studied, with the most frequent diagnoses being allergic rhinitis, headache in adults, and atopic dermatitis and multiple recurrent infections in children. Disease severity decreased significantly over this time, with considerable improvement in physical and mental quality of life. Another prospective multicenter observational study of 129 patients treated homeopathically by 48 physicians for low-back pain found sustained physical and quality of life improvements, with decreased use of conventional health care services and pharmacologic therapies.[87] A similar prospective multicenter observational study evaluated symptom changes in 212 adult patients with chronic migraines who were treated with individualized homeopathy by 68 physicians. Migraine severity showed marked improvement at 3 and 24 months, with improved quality of life and decreased use of conventional health services.[88]

Animal Studies: Field and Laboratory Research

In a now classic study, *Caulophyllum* (in the thirtieth centesimal potency) was given to 10 sows to test its efficacy in the control of stillbirths. The results showed a statistically significant drop in the number of stillbirths and led to a larger, uncontrolled study in a whole herd. After 4 months of therapy, piglet mortality dropped from 20% to 2.6%.[89]

Cloudhury obtained dramatic results from injecting mice intraperitoneally with kali phosphoricum, calcarea phosphorica, or ferrum phosphorica (in the thirtieth decimal potency) 12 days after implantation of fibrosarcoma. Of the 77 treated mice, 52% were cured and survived more than 1 year, whereas all of the 77 controls died within 10 to 15 days.[90]

Scofield, in his review article, discussed numerous experiments with humans, animals, and plants using isopathic treatment for poisoning and experimental liver damage and various in vitro studies.[13]

A number of studies have been conducted to investigate the ability for homeopathic preparations to effect either the elimination or consequences of toxic substances.

There is good evidence that homeopathy may be effective in assisting in the elimination and treatment of heavy metals and other toxins. Studies of arsenic,[91,92] bismuth,[19,20,93] lead,[94] mercury,[95,96] carbon tetrachloride,[21,26] a-amanitine (from the mushroom *Amanita phalloides*),[27] and carcinogens such as 2-acetylaminofluorene and phenobarbital[97] have been published.

The use of homeopathic dilutions of hormones and immunomodulators have shown potential. Immunostimulatory effects of high dilutions of thymic hormones and interferons were demonstrated in mice by Bastide's group.[27,98-101] Other studies demonstrated that extremely small amounts of antigens were specific for immunomodulation.[102-106] In one study, half of a group of mice were given preparations of reticuloendothelial tissue from *F. tularensis*-infected mice in six different serial agitated dilutions (SADs), three of which were beyond Avogadro's number in terms of molecular content. The other half of the group of mice were given control dilutents. All mice were then challenged with lethal doses of *F. tularensis* and evaluated for time to death and total number of deaths per group. The SAD preparations resulted in increased mean times to death (18.6 vs 13.7 days) and decreased mortality (53% vs 75%). The protective effect was not related to the level of dilution of substance.[106]

Magnani et al used a well-designed mouse model to examine the anxiolytic-like activity of several potencies of ultra-diluted *Gelsemium sempervirens*, compared with the drug buspirone and placebo. *Gelsemium*-treated mice spent more time in a lighted compartment (a measure of reduced anxiety), similar to the effects of buspirone and significantly greater than the placebo group. The authors concluded that *Gelsemium* acted on the emotional reactivity of mice, with anxiolytic-like effects even at ultra-high dilutions.[107]

These and other such dramatic results have tremendous implications in pharmacy, immunology, and clinical health care that demand continued research.

Basic Research

Clinical and experimental data obtained in studies about the effect of homeopathic preparations in inflammatory conditions present a considerable degree of reproducibility.[108-112]

The inability of Ovelgonne et al[113] and Hirst et al[114] to replicate their study published in the journal *Nature*, using the human basophil degranulation test (HBDT) to establish the ability for high dilutions to trigger the degranulation of anti–immunoglobulin-E caused considerable distraction from other more credible research.

Brown and Ennis[115] used different methods to demonstrate the efficacy of high dilutions of histamine to inhibit the activation of basophils using HBDT. Instead of measuring degranulation provoked by ultramolecular dilutions of anti–immunoglobulin-E, as Ovelgonne et al and Hirst et al did, they examined the inhibition of activation of basophils by ultramolecular dilutions of histamine.

The experiments used ultramolecular dilutions of histamine (15 to 19 c), prepared with vortexing (instead of succussion).

The main experiment, performed by all the laboratories, was based on inhibition of basophil activation as measured by degranulation. Flow cytometry experiments at three laboratories showed compatible results, with inhibition of activation as high as 43%. Nearly all experiments showed statistically significant inhibition of basophil activation.[116-119]

Experimental study of homeopathy in allergology[120] effects have been reported in vivo,[121-123] as well as in vitro.[124-128]

The physical properties of homeopathic preparations are gaining considerable understanding via research. Studies demonstrated that the physicochemical properties of extremely diluted solutions (EDS) are different from those of pure untreated water, notwithstanding the identical chemical composition of the two liquids.[129-131] The same conclusions were inferred by Lo.[132,133] Rey[134] showed that the structure of hydrogen bonds in pure water was different from that of an EDS obtained by an iterative procedure of successive dilutions and succussions, and was not identical as expected. Recent studies on the physicochemical properties of water provided evidence that the most studied liquid by far, water, still exhibits unexpected properties.[135-141] Lobyshev et al[142] showed that low concentrations and electromagnetic fields can produce large-scale realignments of its structure, which can be either reversible or irreversible. One can deduce from these studies that water and aqueous solutions are complex systems, capable of auto-organization as a consequence of small perturbations of various kinds.

The question of whether water can maintain "memory" of solutes in EDS is best understood by understanding the physical characteristics of water and its ability to form stable clusters and crystals. This aspect of physics is not widely studied but is well documented.[129-132,135,140,143]

Sukal et al[144] pointed out that ethanol molecules, via which potentized homeopathic substances are prepared and stored, are thought to promote or preserve water structures in the potentized substance. These researchers examined the Fourier transform infrared spectra of various ultra-diluted homeopathic substances—*Nux vomica* 30C, *Lycopodium* 30C, *Santonin*, 30C, *Cina* 30C, *Cina* 206C, and *Cina* 1006C—as well as their diluent media, 90% ethanol and ethanol 30C. The potencies differed from each other, and from their diluent media, in the number of oxygen–hydrogen bending vibrational bands, as well as their wave number, shape, and halfwidth of the bands. This study illustrated that medicated sucrose globules used in homeopathic practice can retain specific spectral properties and can be differentiated from each other by Fourier transform infrared spectra with regard to the oxygen–hydrogen bending vibrational band.[144]

Such meticulously designed and executed studies are bringing us ever closer to understanding the mechanisms by which homeopathy may work.

SUMMARY

Homeopathy plays an important role in the context of modern naturopathic medicine. Hahnemann emphasized the importance of lifestyle in the treatment of the patient. One of his primary dictums was to first remove the obstacles to cure, as he said:

> *While taking a case of chronic disease one should examine and weigh the particular conditions of the patient's day to day activities, living habits, diet, domestic situation, and so on. One should ascertain whether there is anything in them which may cause or sustain the disease and remove it to help the cure.*

Unfortunately, homeopathy is also an extremely challenging system to master, requiring both considerable understanding of case taking and materia medica, as well as extensive consultation time with the patient. It has therefore often been discarded, even by those aware of its efficacy. Although attempts have been made to reduce it to simpler systems (e.g., allergy desensitizations, vaccinations, Schuessler's cell salts, and isopathic preparations from diseased tissues and heavy metals), they are not considered strictly homeopathic unless prescribed according to their effects upon healthy people or the confirmed observations of cured symptoms.

The greatest challenge to homeopathy is not how it fits into the current scientific paradigm, but how it fits into health care. The same biases against homeopathy have been used against other nonpharmacologic approaches to medicine, including psychology and nutritional medicine.

The wide acceptance in the homeopathic community of unaccredited educational programs has favored the spread of nonclinically trained homeopaths. Naturopathic medical schools in the United States have remained one of the few resources for clinical training in homeopathy. Homeopathic medical schools in other countries have maintained homeopathy in the context of medical and clinical training.

There have been many individualized styles of prescribing introduced into homeopathy that have created breaches between different practitioners. In addition, many new medicines are being introduced without adequate clinical verification. Unfortunately, there are few forums for critical discourse within the homeopathic community.

The divisions between different schools of homeopathic practice are attempts to parlay new ideas against an orthodox view that solely seeks to maintain the integrity of principles developed by Hahnemann.

One basic argument by some of these schools has been that because a homeopathic prescription should not be based on a specific disease, extensive training in current medical sciences would not be primary. However, this ignores an essential part of Hahnemann's instructions. In the third paragraph of the *Organon* he stated, "The physician should distinctly understand…what is curable in diseases in general, and in each case in particular; that is, the recognition of disease."

Correct diagnosis is primary in understanding the context and pathogenesis of a disease. So it would not be possible to understand the relation of much of drug proving symptoms, their clinical application, and the evaluation of efficacy or subsequent case management without understanding the nature of disease. Homeopathy is proven in the context of good health care. It is a system of therapeutics, not a replacement for common standards of diagnosis and preventive care.

Homeopathy is representative of a principle found throughout nature and its role in bringing forth concepts of resonance, constitution, and holism are shared throughout fields of science and healing. Homeopathy represents an integrated holistic system of natural therapeutics. Its capacity for addressing psychosomatic disease and acute pathology as a dynamic process is unique. It has remained a coherent system, with extensive clinical verification, for more than 2 centuries. Homeopathy is an economical and effective method that has been established as an integral part of the medical system in many countries. With the resurgence of interest in natural medicine, this discipline will undoubtedly be more widely used.

INTRODUCTION

Hydrotherapy may be defined as the use of water, in any of its forms, for the maintenance of health or the treatment of disease. It is a cornerstone of naturopathic therapeutics, drawing on the vitalistic roots of the nature cure tradition as it stimulates the body's inherent self-healing mechanisms. The power of hydrotherapy is demonstrated by the persistence of its use now, two centuries after it was first systematized as a therapeutic modality in Western medicine. Naturopathic colleges and universities universally teach hydrotherapy as a core therapeutic modality and utilize it in their teaching clinics on general medicine, physical medicine, and specialized hydrotherapy shifts. Practicing naturopathic physicians utilize hydrotherapy widely in their practices, with some notable doctors, such as Cathy Rogers, ND; Nancy Welliver, ND; and Letitia Dick-Kronenberg, ND; having long-standing practices that emphasize hydrotherapy as their primary therapeutic modality. Additionally, many students at the various naturopathic colleges and universities seek preceptorships and supplementary education specific to hydrotherapy, as well as organizing campus clubs designed to give students greater exposure to and experience with this powerful medicine.

In his original chapter in the first edition of the *Textbook of Naturopathic Medicine*, Dr. Barry wrote: "Although one of the oldest known therapies, it [hydrotherapy] has received little attention from the research community, particularly recently. Much of the information presented here is compiled from older works which, although they lack the quantification available with current technology, show a remarkable attention to clinical effects and patient response." What these older works tell us about the uses and effects of hydrotherapy and the specific details of the means employed is invaluable, and physicians practicing hydrotherapy will find its greatest effectiveness by mining the wisdom of the original practitioners of Western hydrotherapy. For example, the individualization of a particular treatment to suit the vitality, or lack thereof, in each patient, must be attended to for treatments to have their greatest impact. It is this need for individualization that, like other aspects of holistic medicine, confounds the conducting of modern hydrotherapy research. However, in the last few years, attention has increased around the topic of hydrotherapy research and practice.

HISTORY

As one of the ancient methods of treatment, hydrotherapy has been used to treat disease and injury by many different peoples, including the Egyptians, Assyrians, Persians, Greeks, Hebrews, Hindus, and Chinese. For example, in the *Riga Veda*, circa 1500 BC, we read that "water cures the fever's glow."

Hippocrates used hydrotherapy extensively around 400 BC, and his writings concerning baths contain some of the earliest dictums on the therapeutic uses of water[1]:

> *In general it suits better with cases of pneumonia than in ardent fevers; for the bath soothes the pain in the side, chest and back; cuts the sputum, promotes*

*Editor's Note: We would like to acknowledge the foundational contributions to this chapter as authored originally by Robert Barry, ND, in the first and second editions, and updated by Doug Lewis, ND, for the third edition of the *Textbook of Natural Medicine*.

expectoration, improves the respiration, and allays lassitude; for it soothes the joints and outer skin, and is diuretic, removes heaviness of the head, and moistens the nose.

As these early writings show, the healing effects of water were observed and used therapeutically for centuries before the modern hydrotherapy movement. Modern hydrotherapy has had many contributors, including Sir John Floyer, William Winternitz, Johann Schroth, Johann Hahn, and J.H. Rausse to name a few.

Naturopathy grew out of the hydrotherapy movement, which traces its roots to two prominent hydrotherapists: Vincent Priessnitz of Austria and Father Sebastian Kneipp of Bavaria. Neither had formal medical training, but learned their craft through personal experience and astute observation. Priessnitz observed wounded animals bathing in cold water and was inspired to heal his own broken ribs using cold compresses. Father Kneipp healed his tuberculosis after reading Johann Hahn's Lectures on the *Wonderful Healing Power of Fresh Water.*

Priessnitz opened his first hydrotherapy institution at Grafenburg in 1826 and successfully treated over 40,000 people with little loss of life. Many of his patients were very ill and unable to be helped by medical doctors. He was arrested many times for practicing medicine without adequate training but eventually was given all the privileges of a medical doctor because his treatments were so effective.

Father Kneipp became an ordained priest in 1852 and was assigned as a chaplain to a number of parishes. He began using the water cure to treat his parishioners who were unable to be helped by medical doctors. Although church leaders did not approve of his practices and forbade him continuing, still he continued. He was transferred to Worishofen, where his successes became known, and people came from near and far to receive the cure. He never charged for his services, believing care should be available to anyone in need. His first book, *My Water Cure,* was written for the common people in clear and plain language and is an excellent instructional manual for anyone interested in hydrotherapy today.

Priessnitz's philosophy of water cure was brought to the United States in the mid-nineteenth century. Joel Shew, a medical doctor from New York, studied with Priessnitz and returned to the United States to start a hydropathy institute based on his teachings. An associate of Shew's, Russell Trall, MD, started his own hydrotherapy institute in Manhattan in the 1850s and later published the *Hydropathic Encyclopedia*. John Harvey Kellogg attended Trall's institute, and in 1900 published *Rational Hydrotherapy,*[2] in which he considered the physiologic and therapeutic effects of water, along with an extensive discussion of hydrotherapeutic techniques.

There were other notable individuals who were influenced by Priessnitz's water cure philosophy. Robert and William Wesselhoeft studied with Priessnitz and opened a sanitarium in Vermont after immigrating to the United States from Germany. David Ruggles, a black abolitionist who was treated by the Wesselhoefts, opened his own clinic; his patrons included fellow abolitionists Sojourner Truth and William Lloyd Garrison. Mary Gove Nichols, a woman denied any formal education but with a keen interest in medical science and determination to learn, opened her own institute in New York in 1845. She studied with both the Wesselhoefts and Joel Shew.

Benedict Lust, considered to be the father of naturopathy, was successfully treated by Father Kneipp and was charged with introducing the water cure to the United States. Lust successfully combined water cure with other nature cure modalities, establishing the foundation of naturopathic medicine. Henry Lindlahr, a wealthy U.S. banker suffering from diabetes, visited Kneipp after being told by his physicians that there was nothing they could do for him. He was put on a strict diet and daily regimen of cold water treatments. Once cured, he returned to the United States, completed medical training and opened a sanitarium in Chicago in 1906. He believed the vis medicatrix naturae was the true physician and wrote *Nature Cure,*[3] the definitive guide to the philosophy and practice of nature cure medicine.

Otis G. Carroll, one of the modern forefathers of naturopathic medicine, studied with Lindlahr and Alex Ledoux, another student of Sebastian Kneipp. He pioneered constitutional hydrotherapy, the combining of compresses with electrical stimulation, believing this therapy changed the constitution of the body's cells. Carroll's work was continued by Harold Dick, a naturopath in Spokane, Washington. His daughter, Letitia Dick-Kronenberg, worked with her father after completing her studies at the National College of Naturopathic Medicine and continues to practice and teach the hydrotherapy practices passed on to her.

Hydrotherapy has a long, rich history, and naturopathy is rooted in its practice. Thus, it is still taught in naturopathic educational institutions and practiced in their associated teaching clinics as a highly effective, fundamental naturopathic modality.

PHYSIOLOGIC EFFECTS OF WATER

The physiologic effects of hydrotherapy may be classified as thermal, mechanical, and chemical. Thermal effects are produced by the application of water at temperatures above or below body temperature. The greater the variation from body temperature, the greater the effect produced, other factors being equal and allowing for individual patient variability. Mechanical effects are produced by the impact of water acting on the body surface in the form of sprays, douches, frictions, immersions, whirlpools, etc. Chemical effects are produced when water is taken by mouth or used to irrigate a body cavity, such as the large colon. Thermal effects are the most commonly used therapeutically and are, thus, the main subject of this chapter.

In general, hot relaxes and sedates, whereas cold stimulates, invigorates, and tonifies. However, very hot can stimulate and also be destructive, whereas prolonged cold can be depressive and destructive. A comparison of the effects of hot and cold on several body systems is given in Table 40-1.

Principles of Blood Movement with Hydrotherapy

To promote healing, either locally or systemically, it is important to maximize circulation of well-oxygenated, nutrient-rich blood, which also has the effect of carrying away metabolic and other waste products. Hydrotherapy techniques are one of the most effective means of accomplishing this, especially when used in conjunction with proper levels of activity, optimal nutritional intake, and adequate detoxification.

Using different temperatures of water, one can either increase or decrease the rate of blood flow (BF) through an organ or area of the body and can either increase or decrease the total volume of blood in an organ or area of the body, according to whether the area is anemic or congested. To accomplish these changes, five relevant physiologic principles must be considered:

- Revulsive effect
- Derivative effect
- Spinal cord reflex

TABLE 40-1 **Comparison of the Effects of Hot and Cold on Several Body Systems**

SYSTEM/ORGAN	COLD		HOT
	PRIMARY	SECONDARY	
Skin			
• Blood vessels	Constriction	Dilation	Dilation
• Respiration	Decreased	Increased	Increased
• Heat loss	Decreased	Increased	Increased
Blood vessels	Constriction	Dilation	Dilation (constriction if intense)
Heart	Rate increased	Rate decreased	First decreased, then increased
Nerves	Numbed		Excited
Muscles	Volume decreased		Volume increased
Respiration	Slowed and deepened		Rate increased
Stomach	Motility and HCl increased		Motility and HCl decreased

HCl, hydrochloride.
Modified from Kellogg JH. Rational hydrotherapy, ed 4, Battle Creek, MI: Modern Medicine, 1923:721-722.

- Collateral circulation
- Arterial trunk reflex

Revulsive Effect

The revulsive effect provides a means of increasing the rate of BF through an organ or area of the body and is most effectively accomplished using contrast hydrotherapy: alternating hot and cold in the form of compresses, baths, showers, sprays, etc. Local contrast applications produce marked stimulation of local circulation. A 30-minute local contrast bath produces a 95% increase in local BF when the lower extremities alone are immersed. When all four extremities are immersed at the same time, there is a 100% increase in BF in the upper extremities and a 70% increase in the lower extremities.[4]

Contrast applications to the area of skin that is in a reflex relationship (see Spinal Reflex Effect, following) to an organ increase the functional activity of that organ. Hence, liver function is increased by contrast application over the right upper quadrant of the abdomen.

Several studies have researched the optimal treatment times for revulsive effects. Woodmansey et al[5] found 6 minutes of hot application and 4 minutes of cold to be optimal for the British subjects he studied. Krussen[6] found 4 minutes of hot and 1 minute of cold to be the best treatment protocol. Moor[7] stated that 3 minutes of hot followed by 30 to 60 seconds of cold provided satisfactory clinical results. These variations create an inference that, due to variations in patients and locales, it is best for practitioners to determine their own ideals, based on their own observations of clinical results. Most importantly, the cold application needs to be long enough to produce vasoconstriction, which can occur in as short a period as 20 seconds. Additionally, the course of treatment should always end on cold to discourage congestion in the area.

Repetition of applications is another important variable to consider when applying revulsive treatments. A series of three hot/cold applications seems to be practical. Most individuals show a decreasing reaction to repeated applications of cold.

The revulsive effect is ideal for treating situations presenting primarily as congestion, for example, the use of alternating hot/cold compresses over the face for sinus congestion. As a powerful decongestant, the revulsive effect also acts as an analgesic for pain resulting from congestion. Because of its marked stimulation of local circulation, the revulsive treatment is an exceptionally effective hydrotherapeutic procedure, and one of the most generally useful considering its simplicity.

Derivative Effect

Congestion can also be treated using the derivative effect, which moves blood from one area of the body to another. This effect is best obtained by the prolonged use of either cold or heat, depending on whether one wants to draw blood into an area (hot application) or to drive blood out of an area (cold application). For example, prolonged application of heat to the feet, as with a hot foot bath, will decrease congestion in the head by increasing BF to the feet. Alternatively, a cold compress can be applied to the forehead or back of the neck to restrict BF in the head, or the two treatments can be combined for even greater effect. This form of treatment is often quite effective for certain forms of congestive headaches.

Spinal Reflex Effect

A sufficiently intense local application of hot or cold not only affects the immediate skin area but also causes remote physiologic changes, mediated through spinal reflex arcs (see Moor[7]), thus providing a means of affecting a distant area of the body through a local application. These effects have been carefully observed over many years and have led to a mapping that correlates each surface area with a corresponding internal area and/or organ. Most texts on hydrotherapy contain such a diagram.[2,7]

Hewlett,[8] Stewart,[9] and Briscoe[10] all noted changes in BF in the opposite arm and hand when one arm and hand were placed in hot or cold water. Poulton[11] demonstrated that esophageal function could be influenced by irritation of the skin over the sternum. Bing and Tobiassen[12] showed reflex relationships between the skin of the abdominal wall and the colon. They also demonstrated a reflex relationship between the lungs and the skin of the chest wall.

Fisher and Solomon[13] stated: "externally applied heat not only decreases intestinal blood flow, but also diminishes intestinal motility and decreases acid secretion in the stomach, while cold has the opposite effect." This is an example of a contrary effect, in which the reflex effect is the opposite of that observed in the local reflex skin area (i.e., local heat increases BF to the local skin, but decreases BF to the reflex organs).

Tables 40-2 to 40-4 show some of the observed reflex effects of hydrotherapeutic procedures.[7]

Collateral Circulation Effect

The collateral circulation effect may be considered a special case of the derivative effect.[2] In general use, the derivative effect involves blood volume changes from one area of the body to another, as previously discussed. The collateral circulation effect, in contrast, more specifically considers the local circulatory effects on deep (rather than superficial) collateral branches of the same artery.

Considering the circulatory patterns of a large body part, such as the thigh, it is clear that both superficial and deep areas are

TABLE 40-2 **Reflex Effects of Prolonged Heat**

APPLICATION LOCATION	EFFECT
One extremity	Vasodilation in contralateral extremity
Abdominal wall	Decreased intestinal blood flow, intestinal motility, and acid secretion
Pelvis	Relaxes pelvic muscles, dilates blood vessels, and increases menstrual flow
Precordium	Increases heart rate, decreases its force, and lowers blood pressure
Chest	Promotes ease of respiration and expectoration
Trunk	Relaxes ureters or bile ducts and relieves renal or gallbladder colic
Over kidney	Increases production of urine

TABLE 40-3 **Reflex Effects of Prolonged Cold**

APPLICATION LOCATION	EFFECT
Trunk of an artery	Contraction of the artery and its branches
Nose, back of neck	Contraction of the blood vessels of the feet and hands and nasal mucosa
Precordium (ice bag)	Slows the heart rate and increases its stroke volume
Abdomen	Increases intestinal blood flow, intestinal motility, and acid secretion
Pelvic area	Stimulates muscles of the pelvic organs
Thyroid gland	Contracts its blood vessels and decreases its function
Hands and scalp	Contraction of brain–blood vessels
Acutely inflamed areas	Vasoconstriction and relief of painful joints or bursae

supplied by the same artery. A hot application to this area dilates the surface vessels, drawing blood to the superficial areas and concurrently decreasing the BF to the deep areas. A cold application causes the opposite effect. Local compresses and fomentations are the most commonly used techniques to affect collateral circulatory changes.

Arterial Trunk Reflex

The arterial trunk reflex effect is a special case of the general reflex effect.[2] Prolonged cold applied over the trunk of an artery produces contraction of the artery and its branches distal to the application. Prolonged hot applications have the opposite effect, producing dilatation in the distal arterial bed. For example, prolonged cold application over the femoral artery in the groin will decrease BF in a foot or ankle with an acute injury involving either internal or external hemorrhage. After the acute phase, prolonged hot applications can be used to increase circulation and speed healing of the injured part.

Local and Systemic Effects of Cold Applications

Local cold applications produce vasoconstriction in the local tissues, leading to a decrease in local circulation. If the cold application is long, intense, and covering a large enough area, a slowing of the general circulation may occur. The migration of leukocytes and inflammatory agents from the vascular system into the local tissues and local metabolic activity are decreased, leading to a more moderated healing response to acute injury. Nerve conduction velocities are diminished, resulting in decreased sensation, including pain, as well as slowed motor response. Muscle tissue tends to contract, and connective tissues become less plastic. Thus, cold applications may assist in the tonification of muscle tissue, leading to benefits such as increased urinary sphincter tone. General applications of cold are hypothermic and produce a peripheral vasoconstriction with shunting of the blood to the core.

TABLE 40-4 **Reflex Effects of Short Cold**

APPLICATION LOCATION	EFFECT
Local application of intense cold as brief as 30 s	General peripheral vasoconstriction
Face, hands, and head	Increase in mental alertness and activity
Precordial area	Increase in heart rate and stroke volume
Chest, with friction or percussion	Initial increase in respiratory rate, then slower, deeper respiration

Water temperatures below 50°F are considered very cold and may be depleting to many patients if used generally, although ice packs can be an effective local treatment for swelling and pain. Temperatures between 50°F and 70°F are considered cold and are often the more desired range for many cold water treatments.

Cold applications are often prescribed for the relief of pain. Saeki[5] found cold, but not hot, applications to be useful in the relief of prickly pain sensations experimentally induced in study subjects. Pain sensations were measured on the visual analog scale, and skin BF and skin conductance levels (SCL) were also measured. Cold applications decreased pain, BF, and SCL, whereas hot applications increased pain, BF, and SCL.

In 2002, a small (19 patients) study entitled "To Evaluate the Effect of Local Application of Ice on Duration and Severity of Acute Gouty Arthritis" was published.[14] Treatment and control groups both received oral prednisone 30 mg tapered to 0 mg over 6 days and colchicine 0.6 mg daily. The treatment group received daily ice applications, whereas the control group did not. After 7 days, treatment group participants had a significant reduction in pain compared with the control group.

Cold water is very effective in lowering body temperature caused by fever due to illness or increased core temperature from exposure or exercise. Cold sponging has often been recommended for the reduction of fevers in children. Two articles published in 1997[15,16] compared the use of sponging to oral antipyretics. Both studies concluded that sponging was more effective than medication in the first 30 minutes, but after that, the antipyretic medications were more effective. This makes sense, because it takes time for the medications to be absorbed and circulate in the body, whereas the body responds immediately to the application of water to the skin. One of the primary precepts of naturopathic medicine is to work with the vis medicatrix naturae, and fever is one of the body's responses to acute illness, assisting in the healing process. Lindlahr stated, "every so called acute disease is the result of a cleansing and healing effort of nature."[3] The benefit of sponging to reduce fever versus use of antipyretic medication is the ability to better control how much we reduce the fever, if at all.

After a cold application, a secondary, or indirect, effect occurs, also termed the "reaction." This effect is in contrast to the primary effects, as the body responds over time to the general decrease in circulation from the application of cold. Secondary effects include peripheral vasodilation, increased white blood cell and red blood cell circulation, increased metabolism, increased muscle tone, and sense of vigor and well-being. If the cold application is a short one, the reaction follows quickly, its intensity reflecting the intensity (i.e., coldness) of the application. The reaction to a brief cold application produces a slowing of the heart rate with a mild increase in blood pressure. The secondary effects are what is utilized primarily in nonacute cold water treatments.

Local and Systemic Effects of Hot Applications

Heat may be applied to the body in various ways, including hot packs, fomentations, steam, baths, and showers. All hot applications produce physiologic responses that are attempts by the body to eliminate heat to prevent a damaging rise in local and systemic temperatures. The effects produced by hot applications depend on the mode, temperature, and duration of the application and the condition of the patient.

Water at 98° F or above is generally perceived as hot, and water higher than 104° F is considered very hot. At 120° F, an immersion bath becomes unendurable, although small areas of the body, such as the hand, may be conditioned to endure a temperature of 10° to 15° higher for short periods. The mucus membranes, unlike the skin, may endure temperatures as high as 135° F, which accounts for our ability to drink very hot liquids or benefit from steam inhalation treatment. Although exposure to the high temperatures of hot tubs and saunas has become quite popular in recent years, Kneipp, Preissnitz, and Kellogg all believed that repeated and prolonged use could weaken the individual unless counteracted by frequent cold applications, such as showers or ablutions.[2]

Local hot applications result in vasodilation, with resulting increase in capillary BF, oxygen delivery to the tissues, local metabolic activity, and migration of lymphocytes through vessel walls and into the local tissues. Local sweating is increased, and muscle relaxation occurs. Intense moist heat applied for a long period of time (several minutes) has a depth of penetration not exceeding about 3.4 cm. The increased BF through the area carries away heat conducted into the tissues from a hot application and limits the depth of penetration. (This "radiator-like" effect can be overcome by more intense applications of heat, and deep tissue destruction can occur.)

General hot applications can have dramatic effects on the cardiovascular system. Peripheral dilation occurs with a marked increase in BF (as much as 400%), pulse rate (6 to 10 beats/min per 1° F rise in body temperature) and pulse pressure, and a decrease in cardiac stroke volume. Respiratory rate increases 5 to 6 breaths/min per 1° F rise in body temperature. Hyperventilation may occur and result in respiratory alkalosis. The blood volume increases as a result of the uptake of fluids from the tissues, leading to a decrease in the hematocrit. A transient leukopenia occurs in the first few minutes after a hyperthermia treatment, followed thereafter by leukocytosis. Sweating increases, leading to a loss of water, salt, urea, uric acid, creatinine, sulfates, lactic acid, and other metabolites.

A 2009 study of congestive heart failure patients showed improved biventricular cardiac function, increased output, decreased heart rate, and decreased blood pressure during warm water therapy over an 8-week period. The beneficial effects were found statistically significant during the therapy but did not change cardiac function overall. Authors concluded that warm water therapy is safe for patients with congestive heart failure.[17] Similarly, a 2003 study showed improved mood, physical capacity, enjoyment, and heart failure-related symptoms (subjective), as well as significant decreases in heart rate and rate–pressure product at rest in patients with congestive heart failure. This study used warm water baths and cold water pours, which might account for the sustained therapeutic effect.[18]

In addition to the local hot applications discussed in previous sections, local hot applications are common and varied. For example, inhalation of steam for the treatment of the common cold has often been prescribed. Four studies[19-22] published between 1987 and 1994 demonstrated the benefit of steam inhalation for nasal symptoms, with one of these studies[21] demonstrating a decrease in inflammatory mediators in the local tissues.

A recent study of the treatment of benign prostatic hypertrophy using thermotherapy demonstrated a significant decrease in bladder outlet obstruction by using heated water in a closed loop catheter system.[23] A Cochrane Review[24] of interventions for chronic abacterial prostatitis concluded: "The routine use of antibiotics and alpha blockers for chronic abacterial prostatitis is not supported by the existing evidence. The small studies examining thermal therapy appear to demonstrate benefit of clinical significance and merit further evaluation."

Physicians do not normally think of hot applications in the treatment of acute sports injuries. However, one recent study[25] compared the use of hyperthermia to therapeutic ultrasound. In comparing 21 randomized patients with acute muscular injuries of different sites and severity to 19 controls, researchers discovered that after 2 weeks of treatment, the hyperthermia group had significantly less pain and faster hematoma resolution.

The presence of fever has long been associated with better survival and shorter duration of disease in cases of infection. Although the concept of modulating fevers in acute illness using sponging rather than antipyretics was discussed previously, hydrotherapy can also be used to enhance or induce a fever in acute or chronic infections to mimic or increase the body's natural infection fighting capacity. Many studies have demonstrated the causes of that beneficial response. Four studies reviewed for this chapter[26-29] demonstrated the activation and mobilization of blood mononuclear cells with hyperthermia treatments. One of these studies[26] demonstrated significantly increased serum cortisol, plasma norepinephrine, and plasma epinephrine, and hypothesized that these elevated stress hormones were responsible for the rise in mononuclear cells. One study[28] concluded that "fever-induced Hsp70 expression may protect monocytes when confronted with cytotoxic inflammatory mediators, thereby improving the course of the disease."

GENERAL GUIDELINES FOR HYDROTHERAPY

1. The first rule of hydrotherapy is the same as for any therapy: treat the whole person. This involves considering all aspects, including medical history, current condition, current medications, and any other relevant information.
2. Use hydrotherapy treatments in a coordinated and integrated manner with any treatments or medications the individual is receiving.
3. To provide as precise a treatment as possible, grade the patient in terms of age, severity of problems, vitality, emotional state, circulatory condition, etc. A patient's body temperature, along with their subjective general feeling of warmth or chilliness, should be used as a guide as to how intense the hot or cold used in a treatment should be. Be especially careful with young

or elderly persons, and individuals who are chilly, have cardiac problems, are weak or debilitated, are obese, or have other severe physical compromises.
4. If a patient becomes chilled during a treatment, it may be necessary to stop the treatment and warm the person. Sometimes it may suffice to warm the person (by such means as hot drinks, friction rubs, additional blankets, or a hot water bottle to the feet) while continuing the treatment. If the person fails to warm after these attempts, then stop the treatments and warm him or her. Never allow a patient to become chilled to the point of shivering.
5. After a hydrotherapy treatment, avoid excessive heat or cold and/or drafts. The patient should be warmly dressed but not overly so.
6. It is best to do the treatment at an optimal time of day for that patient. It is best to do treatments before meals or at least one hour after a meal.

As with any therapy, it is important to practice hydrotherapy with a critical eye, noting unusual reactions and physiologic effects. Many physiologic parameters, such as urine chemistries and microscopic components, specific gravity, body temperature, and blood sugar levels, may be easily monitored and recorded during treatment. This information helps to optimize the treatment protocols, stimulates further research, and validates hydrotherapy as an effective and useful therapeutic modality.

Cautions and Contraindications

Although hydrotherapeutic procedures are generally low force and gentle treatments, they may in some situations produce unexpected or undesired effects. These effects may be the result of improperly applied treatments, but they may, in some cases, result simply from the individual's reaction to the treatment. They may, in the long term, be beneficial. Anytime an individual experiences an undesired effect after a treatment, the therapist should review the treatment's length, intensity, and appropriateness for the individual. If more treatments are considered, they may need to be adjusted to modulate the effects.

Some of the possible side effects of hydrotherapy treatments are headache, vertigo, nervousness, aches and pains, insomnia, hyperventilation, nausea, palpitations, lightheadedness, and chilliness. In most cases, these effects are self limiting and often respond well to simple intervention and/or rest.

If a patient has an adverse reaction, discontinue the treatment and assess the patient's needs. If the patients are chilled, warm them; if lightheaded or dizzy, make sure they are well hydrated, assess for low blood sugar, and allow them to rest. If complaining of headache or nausea, the patient could be detoxifying, so encourage plenty of water and rest. Coaching the person in deep, slow-breathing exercises for several minutes often relaxes them and decreases the reaction.[30] As with any treatment, use professional judgment as to the significance and cause of the patient's response and employ appropriate intervention. Although undesired effects may occur during or immediately after treatments, they may also occur as long as 24 hours later. Therefore, it is important for practitioners to be available to patients during off-duty hours.

Pregnancy

What to do or take in pregnancy is always a concern. Bathing in hot water is no exception. Ridge and Budd,[31] in a letter to the editor of the *New England Journal of Medicine*, summarized these concerns and concluded "that for pregnant (or potentially pregnant) women using a spa pool at a water temperature of 40° C (104° F), any immersion longer than 10 minutes may be too long."

Hypertension and Cardiovascular Disease

Two studies published in 1998[32,33] demonstrated no adverse cardiovascular effects from bathing in water above 40° C and a response to heat stress no different from normotensive subjects.

Cancer

A synergistic effect has been demonstrated with hyperthermia and radiation treatments given in cancer care. Any patient receiving radiation therapy should not be indiscriminately treated concurrently with hyperthermia.

Diabetes

For individuals with insulin-dependent diabetes, the application of heat to the extremities is to be approached with caution. As discussed previously, increased BF with hot application serves to conduct heat away from the area of application. In diabetics with poor circulation to the extremities, less heat is dissipated, and the local tissue temperature rises more than in tissues with normal circulation. It is safer to use less extreme temperatures in individuals with impaired circulation. Additionally, the application of heat increases tissue metabolism. With impaired circulation, tissue metabolic needs can quickly exceed the nutrients and oxygen available from the blood, and cells may die from oxygen depletion.[30] Therefore, very hot applications to the extremities are generally contraindicated in diabetics, whereas mild to moderately hot applications can be quite effective for improving circulation and increasing healing of diabetic ulcers.

For diabetics with conditions in which a hot application to the feet would normally be the treatment of choice but is contraindicated for the patient, a large hot compress to the lower abdomen, groin, and thighs can be used instead to get a reflex reaction in the lower extremities.

Diabetics may also display peripheral neuropathies that decrease their ability to sense heat, thereby increasing the possibility of causing a burn with hot applications. Likewise, individuals with neurologic injury or disease should also be treated with caution during hot applications and be guided to test the water with some part of their body that does not have decreased sensation.

HYDROTHERAPY TECHNIQUES

The various ways in which water may be applied to the human body therapeutically are only limited by the imagination of the practitioner. J.H. Kellogg, in his seemingly exhaustive treatise on hydrotherapy,[2] devoted 541 pages to describing the techniques of hydrotherapy.

Compresses

Compresses are of four basic types: hot, cold, warming, and alternating hot and cold. They are each applied using cloth or other compress material, which is wrung out to the desired amount of moisture and then applied to any surface of the body. A single compress consists only of layers of the wet material, whereas a double compress is one in which the wet cloth is completely covered by dry material, usually wool, which acts to prevent cooling by evaporation or radiation.

Compresses are commonly referred to by the area of the body to which they are applied, such as the throat, head, joint, trunk, or limb.

Cold Compresses and Packs

A cold compress consists of a cloth wrung from cold or ice water and then applied to the body. Some practitioners may add solutes to the water, such as salts. Herbs may also be used to create a more specific effect from the compress. Some commonly used herbs are hayflower, oatstraw, and fenugreek, made as teas into which the compress cloths are dipped. A cold pack is used if the goal is to cool the tissues more aggressively. Packs may be made from crushed ice or purchased as commercially available gel packs that are cooled in the freezer.

Cold compresses are renewed frequently (every one to five minutes) to maintain the primary cold effect, whereas packs remain cold longer. The temperature of a cold compress depends on the specific problem being treated, as well as the state of health of the patient. In general, the colder the application, the shorter the period of application.

The cold pack or compress has primarily a vasoconstrictive effect, both locally and distally. Due to this effect, it may be used to prevent or relieve congestion, reduce BF to an area, prevent edema after injury, inhibit inflammation, and relieve pain due to congestion. It may also be used to reduce body temperature when applied over a large area of the body. Cold compresses should not be used locally in a person who is chilly or who has pleuritis, sinusitis, or acute asthma, as these conditions may be seriously aggravated.

Hot Compresses and Fomentations

The hot compress is a prolonged application of moist heat to a local area of the body. A fomentation is a special type of hot compress that provides prolonged exposure at a higher temperature.

Hot compresses and fomentations have several therapeutic effects. In situations of pain resulting from spasm, they may create an analgesic effect, although this does not hold true for pain resulting from congestion. They also create a derivative effect, increasing BF to the periphery, thereby decreasing internal congestion. By applying short, intensely hot compresses, a stimulation effect may be obtained. This may be used to increase BF to a part, to stimulate certain organ functions, to decrease others, and to produce tissue warming and relaxation. Mildly hot compresses may be beneficial for their sedative effects in treating insomnia, nervous tension, and mild muscular spasms.

Fairly hot compresses may be applied directly to the skin surface, with care taken to not burn or startle the patient. When treating the elderly or those with impaired neurologic function, edema, or decreased circulation, special caution must be taken. Fomentations are commonly applied at temperatures that are not tolerated directly on the skin, and therefore must be applied over a bath towel.

Warming Compresses

The warming compress, also known as the cold double compress, consists of a cold compress covered completely by several layers of dry material, such as flannel or wool, which is allowed to remain on until warmed by the body. The layers of dry material prevent heat loss by evaporation, thereby permitting accumulation of heat. Warming compresses are used most commonly in upper respiratory infections, such as sore throats, bronchitis, influenza, pneumonia, and swollen lymph glands in the neck. They may also be applied over the trunk or abdomen, genital area, joints, limbs, or feet.

A classic example of the warming compress is the wet sock treatment, which is used for congestive headaches, sinusitis, and otitis media in young children. Thin cotton socks are wrung from cold water and pulled onto the feet. These are then covered with a pair of wool socks and left overnight to be warmed by the patient. Frequently, the socks are dry by morning.

The primary effect of the warming compress is to increase local circulation, thereby providing for increased nutrition and oxygenation of the tissues, as well as increased elimination of metabolic waste from the area. In the previous example of wet socks, it is the derivative effect of the treatment that is desired. As with cold compresses, the temperature of the initial application depends on the state of the patient and the condition being treated. In general, the colder the application, the stronger the secondary reaction to the cold. Since weak and debilitated patients are unable to generate a strong secondary reaction, a cool rather than a cold application may be indicated. The same general precautions as for a cold single compress should be followed.

Alternating Hot and Cold Compresses

One of the best ways to increase blood flow through an area is using the revulsive property of water via an alternation of hot and cold. Such treatment starts with a hot compress for 3 to 5 minutes, alternating with a cold compress for 30 to 90 seconds. This sequence is repeated three to five times, always ending with cold. This treatment is very effective for reducing swelling in a joint after an injury or surgery.

Baths

Baths are full or partial immersions of the body into water of various temperatures: cold, hot, neutral, or contrasting. Bath waters may contain additional substances such as salts, minerals, herbs, or medications and may be in an agitated state, as with a whirlpool. In addition to the thermal effects, upon immersion of the body in water, hydrostatic pressure is exerted on the body surface, which has the effect of increasing venous and lymph flow from the periphery and increasing urine output.

Hot Baths

Hot baths are given within a temperature range of 100° F to 106° F for 20 to 60 minutes or longer. They are indicated for rheumatoid arthritis, to aid in relief of muscular spasms, for cleansing the body, to stimulate the immune system, to induce sweating, and many other purposes, and are most useful for producing a hyperthermic response in the tissues or to raise core temperatures. As stated previously, hyperthermia treatments have been found useful in the treatment of infections and malignancies. Water immersions for hyperthermia have the benefit of low cost and more consistent heating of tissues.

When performing local immersions, the water temperature may be as high as is tolerable. The duration of treatment is typically 15 to 20 minutes. Treatment frequency depends upon the status of the patient and the condition being treated.

Whole body immersion at home should be limited to a water temperature of approximately 104° F and not longer than 30 minutes. Patients should have assistance when performing hyperthermia treatments at home.

When hyperthermia treatments are given in the office, close supervision may allow more aggressive treatment. The water temperature may be increased to 106° F, and the duration of treatment may exceed 60 minutes. Patient tolerance is the key to performing safe and effective hyperthermia.

When performing hyperthermia treatments, the following precautions should be observed regardless of whether the treatment is performed at home or in the office:

- Hypotension may result from hot immersions. When arising from the tub, patients may become lightheaded and lose their footing, so caution should be used in rising slowly and having assistance nearby.
- Patients should not take hyperthermia treatments on either an empty or full stomach. Too little food may result in a hypoglycemic episode, and too much food may result in nausea and vomiting.
- Hyperventilation sometimes occurs. On rare occasions patients may go into early tetany from respiratory alkalosis. Being present with the patient and coaching his or her breathing can prevent this.
- Headaches can and often do occur. These can be prevented by the early and frequent use of cold compresses to the head, face, and ears.

The sauna or steam bath can often be used interchangeably with the immersion bath. Immersion, sauna, and steam are most similar with respect to their immune stimulant and detoxification benefits.

In most instances, hot immersions are best followed by a brief cool bath, shower, or spray. Prolonged hot tub baths are never appropriate in the very old or very young, weak or anemic persons, individuals with severe organic disease, or in anyone with a tendency to hemorrhage.

Given for brief periods, they may help to reduce fevers by creating peripheral vasodilation, thereby promoting an increased heat loss.

Neutral Baths

The neutral bath is a full immersion bath given at the average temperature of the skin in which the recipient has neither the sensation of being warmed nor that of being cooled. A minor variation in temperature of as little as 2° F may create a totally different therapeutic effect. Since the ideal temperature depends on the patient's condition and reaction to the water, it is often better to use his or her sensation, rather than a thermometer, as a guide to adjusting the temperature. The duration of a neutral bath may vary from 15 minutes to 4 hours. If the bath lasts longer than 20 minutes, it is necessary to add warm water to maintain the temperature.

The primary effect of a neutral bath is to create a state of decreased excitation. This sedative effect, similar to that produced in deprivation tanks, calms the nervous system. A second effect is activation of the kidneys, creating increased urinary output due to the absorption of water into the body during periods of prolonged immersion.[34] This is aided by the neutral temperature, which provides no stimulus for water loss through sweating. Nephrotic patients display increased phosphate excretion after prolonged immersion; therefore, they warrant special care when given prolonged immersion baths.[35]

Lastly, the neutral bath causes a decrease in the surface temperature of the body due to the lack of the normal heat-producing stimulus of cool air on the skin. As a result, the surface may be cooled as much as 6° F, creating a tendency to chill after the bath. This effect necessitates special care in keeping the patient warm. When prescribed for home treatment, a neutral bath is best taken just before getting into bed to avoid chilling.

Therapeutically, neutral baths are most commonly used for their calming effects in cases of insomnia, anxiety, nervous irritability, exhaustion, or chronic pain. By increasing kidney output, they may be appropriate in detoxification programs for substances such as alcohol, tobacco, or coffee, or as an adjunct treatment for peripheral edema. They also serve a valuable role in the control of fevers in individuals who would not be able to react to stronger measures, such as the very young, very old, feeble, or exhausted.

Cold and Contrast Baths

A local cold immersion bath is an effective treatment for reducing swelling or pain in an area. Rather than a cold compress or ice pack, immersion in a cold bath may be preferable. Full body cold immersion is most often used in combination with hot immersion, since cold alone can be tolerated by only the most robust individuals.

Contrast baths are an excellent treatment for facilitating blood flow and decreasing congestion in any area of the body. As with any contrast therapy, treatment begins with immersion in hot and always ends with cold. With a local bath to the hand, arm, or foot, 3 to 5 minutes in hot and 30 to 90 seconds in cold works well. In the case of full body immersion, the patient often needs at least 10 minutes of immersion in hot, but 30 to 90 seconds in cold is still usually adequate. Local contrast baths can be used much like contrast compresses, increasing BF and decreasing swelling in a local area. Full body immersion improves BF and should be considered in any congested or stagnant condition such as fibroids, dysmenorrhea, amenorrhea, fibromyalgia, hemorrhoids, depression, constipation, edema, benign prostatic hypertrophy, and infertility, to name a few. Local contrast baths are a simple home treatment requiring only two bowls or buckets and water. Contrast full immersion is often done at a spa or clinic, since it requires two large tubs to accommodate both hot and cold water.

Another option for contrast therapy is a shower or affusion. Having patients end their daily hot shower with a full body cold rinse is tonifying to the circulation and immune system. Ernst et al[36] performed a long-term prospective study called "Prevention of Common Colds by Hydrotherapy." The researchers compared 25 volunteers to 25 controls. Volunteers were asked to work up to a 5-minute hot shower followed by a 2-minute cold rinse. The study demonstrated a decrease in both the frequency and intensity of common colds in the treatment group compared with the control group.

Sitz Bath

The sitz bath is a partial immersion bath of the pelvic region. It is more easily given in a specially constructed tub, but may also be effectively done in a regular bath tub. Often it is taken with the feet immersed in a separate tub of hot water before or during the bath. A sitz bath may be taken hot, neutral, cold, or contrasting hot and cold.

The primary effect of the hot sitz bath is analgesic. It may be helpful in cramps of the uterus or ureters, pain from hemorrhoids, ovaries or testicles, sciatica, urinary retention, and after cystoscopy or hemorrhoidectomy. It is followed by cool sponging or affusion of the area. Hot sitz baths are not indicated in cases of acute inflammation but may be appropriate for chronic pelvic inflammatory disease (PID). Hot applications to the pelvis are also contraindicated during menses in most instances.

Neutral sitz baths are more appropriate for situations of acute inflammation, such as cystitis and acute PID, as well as being effective for pruritus of the anus or vulva. The cold sitz bath is given immediately after a warm-to-hot sitz bath for 30 seconds to 8 minutes. It is important to ensure that the water level of the hot bath on the body is at least 1 inch above the level of the cold water. This ensures adequate warming of the area, thereby preventing chilling. Friction rubs to the hips during the cold sitz bath promote an increased reaction. The cold sitz bath is used mainly for

its tonifying effects. It may be used for subinvolution of the uterus, metrorrhagia, atonic constipation, enuresis, atony of the bladder, and chronic prostatic congestion. Because it increases the tone of the smooth muscles of the uterus, bladder, and colon, it lessens the tendency to bleed from the uterus, the lower bowel, and rectum. It is necessary to provide adequate coverings during neutral and cold sitz baths to avoid chilling.

Contrast sitz baths are much like immersion contrast baths but with only the pelvic region submerged in water. As an alternative, the cold application can be performed with a towel wrung from cold water, with the patient standing in the hot bath and pulling the cold towel into the groin, holding it like a diaper for the time prescribed. Care should obviously be taken when standing in a tub of water, especially when standing up from a hot bath. The contrast sitz bath increases pelvic circulation and tone of the smooth muscles of the region. It is indicated in chronic PID, chronic prostatitis, atonic constipation, and other atonic conditions of the pelvis. The strong revulsive effect created increases the BF in the pelvic region dramatically.

Cold Friction Rubs

Cold friction rubs, or ablutions, consist of frictioning the body in a predetermined sequence with cold water. They differ from sponging in that they are more tonifying and are done more vigorously with rougher materials. A woolen bath mitt works well, but if this is not available, a coarse washcloth or loofa may also be used.

The primary effect of a cold ablution is tonic. Therefore, it may be used for any condition in which tonification is desired, such as fatigue after illness or surgery or after hot applications, such as saunas, whirlpools, or hot baths. It is an excellent prophylactic hydrotherapy technique when used regularly along with saunas, hot tubs, and massage.

A whole body ablution is carried out with the patient lying supine, covered completely and not chilly. Using cool to cold water, the therapist dips the mitt into the water and vigorously causes friction on a portion of the body. Depending on the cooling effect desired, the mitt may either be saturated or wrung dry before the friction occurs. The body part is treated until reddening occurs. If the patient is weak, it is best to dry the areas as one proceeds using a coarse dry towel. If the patient is strong and vigorous, one can wait and dry all areas at the end of the treatment.

One sequence for an ablution treatment would be to proceed from the chest to the arms and then the legs, then, turning the patient prone, to do the back of the legs and feet, the buttocks, and finally the back. Only the part being treated is exposed at any time.

Constitutional Hydrotherapy

Constitutional hydrotherapy was, as stated previously, developed by O.G. Carroll as an application of first hot, then cold, to the trunk, both front and back, along with low volt electrical stimulation to tonify the digestive organs and enhance the effects of the water applications. This therapy utilizes both contrast hydrotherapy and warming compress effects. Apart from contrast hydrotherapy applications, it is the most generally useful of the various hydrotherapy treatments and is commonly used to balance body functions, strengthen the immune system, and promote healing, as well as being a useful adjunct to detoxification. A pilot study[37] completed in 2008 at the Bastyr Center for Natural Health on human immunodeficiency virus positive patients showed a statistically significant increase in energy and decrease in body fat and a trend toward increased physical function along with a decrease in pain after a course of treatment with constitutional hydrotherapy. Fifty-eight percent of participants showed a decrease in systolic blood pressure. There was also a sizable decrease in C-reactive protein levels.

Constitutional hydrotherapy may be used as an adjunct to the treatment of any condition. It may be used to treat acute conditions such as upper respiratory infections, bronchitis, asthma, and gastrointestinal infections, and chronic conditions such as irritable bowel, ulcerative colitis, pre-menstrual syndrome, and arthritis, as well as conditions related to nervous system dysregulation such as insomnia or anxiety. (As a general rule of thumb "when in doubt, try constitutional hydrotherapy.") Boyle and Saine's *Lectures in Naturopathic Hydrotherapy* contains an excellent write-up on the constitutional hydrotherapy procedure.[38]

Wet Sheet Pack

The wet sheet pack is one of the most useful of all hydrotherapy procedures. It may be done either in the office or as a home treatment, if adequate direction is provided. It requires from 1 to 3 hours, depending on the patient's condition. Understanding the process completely before using this treatment is important. *Lectures in Naturopathic Hydrotherapy* by Boyle and Saine outlines the wet sheet pack procedure in detail for practitioners.[38]

The wet sheet pack proceeds through four stages: tonic or cooling, neutral, heating, and eliminative. Depending on the desired effect, the therapist may wish to prolong any one specific stage:

- *Tonic stage.* This stage may last from 2 to 15 minutes and is finished when the patient no longer perceives the sheet as being cold. This phase is intensely alterative to the body due to the intense thermic reaction induced. The length of this stage is directly dependent on the amount of water left in the sheet. For weak or exhausted patients, the sheet should be wrung out as completely as possible. For young, strong individuals for whom a more tonifying treatment is desired, more water may be left in the sheet.
- *Neutral stage.* Once the sheet reaches body temperature, the person no longer feels cold. At this time, the neutral phase begins. It may last from 15 minutes to an hour or longer, depending on the vitality of the patient. During this phase, there is a sense of calm that is similar to that experienced during a neutral bath. Often the patient falls asleep during this phase. This stage is indicated in cases of insomnia, anxiety, and delirium. To prolong the neutral phase, provide only adequate covering to prevent the patient feeling cool. Greater amounts of blankets trap more heat, and the neutral phase finishes sooner.
- *Heating stage.* As heat accumulates beneath the blankets, the patient gradually senses the warming and eventually begins to show light perspiration on the forehead. The time between the patient feeling warm and the beginning of perspiration is known as the heating phase. This may last from 15 minutes to an hour.
- *Elimination stage.* The final stage begins when the body begins to perspire. In a febrile patient, this stage is reached sooner. This stage is especially beneficial for those patients in a detoxification process, such as from alcohol, tobacco, coffee, or other toxins. It may also be used with acute infections, such as colds, flu, or bronchitis. Certain conditions that affect the skin, such as jaundice, may also benefit from this stage, as well as acute inflammatory conditions, such as arthritis.

During the elimination phase, it is important to provide adequate fluid to the patient. Herbal teas, used for either their diaphoretic or therapeutic effects, are most appropriate. This phase may last up to an hour. The treatment should be ended quickly if the patient begins to feel chilled or becomes uncomfortable.

The treatment is ended by quickly removing the patient from the pack, frictioning the skin briskly with a dry towel, and having the patient dress. As this is often an intensive treatment, it should be followed with rest or appropriate activity. Lying in a warm room for an hour is an ideal follow-up to this treatment. If done at home, it is best done in the evening just before retiring.

Colonic Irrigation

Colon hydrotherapy utilizes warm water moved through the colon to aid in waste elimination. Colonics are primarily utilized in cases of chronic constipation to both eliminate waste and improve colonic action, or as part of a detoxification protocol supporting excretion of toxins through the gastrointestinal system. The therapy requires a colonic irrigation unit and some training on proper use. Ulcerative colitis, diverticulitis, inflamed hemorrhoids, intestinal bleeding, colon cancer, pregnancy, and hypertension are contraindications to colonic irrigation.

Sauna

Saunas can be wet or dry depending on their heat source. Steam saunas use water as their source of heat and are an excellent general hyperthermic treatment. Saunas have also shown efficacy in detoxification protocols supporting excretion of toxins through the skin. A recent review of the benefits and risks of sauna bathing[39,40] concluded the following:

- It is well tolerated by most healthy adults and children.
- It is safe during uncomplicated pregnancy.
- It may help lower blood pressure and increase left ventricular ejection in patients with congestive heart failure.
- It produces transient improvement in pulmonary function, which may be helpful for patients with asthma and chronic bronchitis.
- It decreases pain and increases mobility in patients with rheumatic diseases.
- It may be contraindicated in patients with unstable angina pectoris, recent myocardial infarction, and severe aortic stenosis.
- It is safe for patients with stable angina pectoris and old myocardial infarction.
- Krop[40] published a case study in 1998 demonstrating the usefulness of sauna in the detoxification of a patient with 20 years' duration chemical sensitivity resulting from low-level exposure to solvents.

SUMMARY

Hydrotherapy provides naturopathic physicians and the general public alike with an effective and inexpensive form of treatment for many conditions, as well as a time-tested method for stimulating the vital force and maintaining health. This chapter has touched on only a few of the many techniques developed over the years. Naturopathic students, patients, and physicians wishing to learn more about the uses and techniques of hydrotherapy are encouraged to read Father Sebastian Kneipp's *My Water Cure* and Boyle and Saine's *Lectures in Naturopathic Hydrotherapy.*[38] Both resources contain instruction in how to use a wide variety of hydrotherapy techniques to regain and maintain health.
